THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

EDITED BY

NORMAN GERALD HORNER, M A , M D

VOLUME II 1930

JULY TO DECEMBER

London:

ED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION
TAVISTOCK SQUARE, LONDON, W C 1

it was not possible to state The infection attacked some part of the intestinal canal, in the majority of cases the small intestine, and was liable to spread upwards, involving the stomach The result of the interference with absorption and secretion was ultimately to produce a condition resembling chronic starvation With regard to etiology, one of the most prominent theories until recently, that of Ashford, that sprue was due to a combination of several factors causing glandular insufficiency, to which was added the organism *Monilia psilosis*, had been disproved by experiments in Bombay, and the theory was losing ground even in the country of its birth

DR P H MANSON-BAHR spoke from his experience of two hundred cases which had been under his care at the Hospital for Tropical Diseases, and showed graphs illustrating the improvement and recovery on a mixed milk high-protein diet Increase of weight in the patient had coincided with a decrease in the size of the stools He believed that sprue was a specific disease, that wherever it occurred it was liable to affect Europeans, and was more prevalent among Europeans the nearer the Equator, though in its distribution sprue missed the whole Central African continent Wherever it occurred, in widely separated localities, the nature and symptoms of sprue were identical It had a definite incubation period, which he reckoned at three months, and it must be assumed that the virus of sprue was capable of lying dormant in the human body for a number of years

DR G M HARSTON spoke of the excellence of ultra-violet radiation in sprue, the best form of apparatus for the purpose was the open tungsten arc DR G W GOODHART raised the question of familial incidence in sprue or allied conditions, and mentioned the case of a patient invalided home from India with pernicious anaemia, which responded to liver treatment, the father of this patient had died of sprue Dr Low, from the chair, said that caution was necessary in appraising any dietetic result, but he highly praised the value of the biochemical work which Dr Fairley had done

ABDOMINAL HYSTEROTOMY

AT a meeting of the Edinburgh Obstetrical Society held on June 11th, with the president, DR H A DAVIDSON, in the chair, DR W F T HAULTAIN reviewed a series of twenty-eight cases of abdominal hysterotomy which had been carried out by the staff of the Royal Maternity Hospital, Edinburgh, during the last three and a half years

Dr Haultain said that as this operation was of recent origin it was advisable to examine statistics to show in what kind of cases it was advocated, and to estimate its value in comparison with other procedures for therapeutic abortion In the cases under review, the most common indication for the operation was severe toxic hyperemesis, the operation having been done twelve times for such cases In five cases it had been done for albuminuria associated with a persistent high blood pressure occurring in the earlier months of pregnancy, in three for toxic pyelitis which had finally been associated with persistent hyperemesis, and in three for myocarditis Twice it had been done in association with myomectomy for degenerating fibroids which had invaded the decidual lining of the uterus It was done once for acute toxic chorea gravidarum, once for a hydatidiform mole, and once for an acute phthisis Only one patient died, a mortality rate of 3·6 per cent., which was thought to be remarkable, as in more than half of the cases the patients were almost *in extremis* with toxaemia before the operation was performed This mortality rate compared very favourably with that in 25 cases of vaginal hysterotomy which had been performed for similar indications during the three years previous to June, 1927, the mortality in these cases was 5—that is, 20 per cent

In comparing the abdominal and vaginal operations, it therefore seemed that the abdominal route was much safer and more successful This was due, in the first place, to the rapidity and ease with which the abdominal operation could be done In the second place, to the absence of severe shock and of bleeding, which was sometimes associated with the vaginal operation Also in cases suffering from dehydration—a frequent cause of death in toxic cases, the abdomen could be filled with saline before closing the peritoneal cavity—this being of very great value to the patient In cases such as severe myocarditis and recurrent albuminuria sterilization could be carried out at the same time With regard to the slower methods of induction of abortion, abdominal hysterotomy would seem to be preferable, especially in primiparae, where induced abortion between the third and sixth months is a most painful and tedious business It was also of special advantage where sterilization had to be carried out It was recommended in cases of hydatidiform mole, for by such an operation the uterus could be completely evacuated of the growth with certainty, and therefore the danger that sepsis, haemorrhage, and chorion epithelioma might develop at a later date would be greatly minimized Up to the present it was not found that the operation had any bad effect on future conception, as one of the patients had had two children since the operation for hyperemesis in 1927

DR C D KENNEDY followed with details of four cases of abdominal hysterotomy which showed the type of case for which the operation was advocated In the first two cases induction was for severe pregnancy toxaemia, in the third for an acute exacerbation of chronic nephritis, and in the last for acute chorea gravidarum The first patient was a primipara, aged 21, who was five and a half months pregnant, and had pre-eclamptic symptoms associated with almost complete loss of vision, urine solid with albumin, and a blood pressure of 220/100 The second was a primipara, aged 21, who was four months pregnant, and was suffering from persistent vomiting She was very emaciated, jaundiced, and mentally deranged, her pulse rate was 144, and her urine contained bile and albumin Conservative treatment was abandoned after five days, because the general condition of the patient was getting worse The third patient, an 8-para, aged 43, was six months pregnant She had pre-eclamptic symptoms with very marked oedema, jaundice, and dyspnoea The urine was solid with albumin, and contained bile and pus cells as well These three patients were operated on under spinal anaesthesia, and made satisfactory recoveries The fourth patient, a primipara, aged 19, was four months pregnant She was very anaemic and suffered from exaggerated involuntary movements of arms and legs The urine contained bile and albumin In spite of conservative measures, the movements increased very markedly She was unable to get any rest at any time during the day or night, she became delirious, and mental symptoms developed rapidly The uterus in this case was evacuated under general anaesthesia, and the patient made an excellent recovery

HABITUAL ABORTION

MISS E V CROWE, reading a paper on habitual abortion, began by stating that this condition was by no means always associated with spirochaetal infection, and that during the past two years there had been 19 non-specific cases treated at the ante-natal department of the Royal Maternity Hospital, Edinburgh In 9 of the cases the abortions were preceded by a full-time, often instrumental, labour Among the 19 cases, 2 were suffering from toxaemia, 5 from cervicitis, 1 from pyelitis, and 2 from valvular disease of the heart All seemed to be suffering from general debility, which made itself manifest by anaemia, emaciation, sallowness, listlessness, headaches, constipation, and loss of appetite and strength All had enjoyed fairly good health until their first pregnancy, after which this chronic ill-health developed The majority of them lived in the poorer districts of Edinburgh, where both fresh air and sunlight may have been lacking The average number of pregnancies was five in the short space of five and a half years—a fact which might be of some significance Dental caries or pyorrhoea was present in 11, and 5 of the patients had septic tonsils All the cases were treated more or less alike by giving them small repeated doses of neokharsivan and a special diet which was rich in calcium, along with any special treatment for the cervix, teeth, etc., which might be required The results were, in the main, satisfactory, but the cases were too few to point to any definite conclusion

KEY TO DATES AND PAGES.

It would appear that a number of false positives were obtained, though, on the other hand, the percentage of positives in active infection was very high, moreover, as the author insists, it is not a single test which is of value, but the curve plotted from a series of tests on a single individual, the curve rises with the infection and falls as it dies down "The reaction appears to be indispensable as a control of specific treatment for tuberculosis" Some observations by other workers follow, with a long list of diseases which may also give a positive reaction—notably typhoid fever, scarlatina, streptococcal septicaemia, and the acute specific fevers in general This reaction is also compared with the complement fixation reaction, and is said to be superior to it

Part II deals with the results in various types of cases, non-tuberculous cases gave an average figure of just under 15, latent tuberculosis had no effect on the reaction (18), ambulatory tuberculosis gave a figure round about 25, whereas in active tuberculosis the figure rose to 50, 60, 100, or more In cases going on to a fatal termination the figures were always high, though immediately before death they fell The author concludes that flocculation increases with the severity of the disease, high figures mean grave lesions and a serious prognosis, while a rise or fall in the curve means increased activity of the disease or improvement respectively In addition, increase in flocculation (that is, a rise in the figure) precedes the clinical signs The broad deductions are as follows (1) Simple infection with the tubercle bacillus does not affect the result of the reaction (2) Active tuberculosis increases the flocculation, no matter what organ or system is involved (3) A chronic lesion may or may not affect the reaction The reaction is often helpful when other examinations, such as clinical, bacteriological, or radiological, fail It tells whether a tuberculous process is progressive, and when it is clearing up It is not a specific diagnostic reaction—only a series of tests, from which a curve may be drawn, is of value

Part III is devoted to B C G vaccination and Vernes's reaction Some account of the vaccine and its mode of administration (by mouth or subcutaneously) is given, together with the classes of persons immunized The serums of 46 such immunized persons gave an average optic density of 21, showing that they did not materially differ from the normal, but definitely might be distinguished from those with active tuberculosis On the other hand, B C G vaccination affects the tuberculin reactions, and may cause nodular local reactions which in 50 per cent of cases go on to the formation of cold abscesses

ADVANCES IN PHYSIOLOGY

THE fourth edition of Professor LOVATT EVANS'S *Recent Advances in Physiology*[1] is sure to receive the usual hearty welcome from teachers of physiology, from clinicians who wish to keep abreast of the subject, and most certainly from senior students who wish to be guided wisely through the maze of current research The two new chapters which have been added deal with the regulation of the coronary circulation and with the functions of the carotid sinus The active interest displayed at present in the problem of coronary occlusion makes the choice of the former topic particularly apt The work of Hering and of Corneille Heymin and his collaborators on the physiology of the carotid sinus is singularly little known in this country—many human anatomists seem to be scarcely aware that this dilatation exists at the bifurcation of the common carotid artery—and the summary given by Professor Lovatt Evans will serve as an admirable introduction to a beautiful regulatory mechanism for controlling blood pressure, cardiac activity, and adrenaline secretion, according to bodily needs

We note with regret that the chapter on tissue oxidation has been dropped We feel sure that this will disappoint many readers—especially teachers of physiology—who have been hoping to receive some help in the elucidation of the intricate results of recent studies in this field It might be mentioned that the position has not been appreciably clarified by the fresh discoveries as to the constitution and properties of glutathione We hope that in a future edition the problem will be reviewed again The chapters which have been retained all show evidence of painstaking revision A helpful account is given of the chemistry of the phosphorus compounds in muscle, and their interrelationships are discussed It now appears that at least six phosphorus-containing compounds exist in muscle and undergo changes during activity—namely, orthophosphates, pyrophosphates, phosphagen, hexose-monophosphoric ester, hexose-diphosphoric ester, and the nucleotides—adenylic and inosinic acid The author concludes, however, that the functions of some of these (especially of phosphagen) are accessory to contraction rather than of fundamental importance No reference appears to be made to the fact that contraction can occur without the formation of lactic acid, though Professor Evans in his discussion expresses scepticism as to whether this substance is as essential as has been hitherto believed

The valuable surveys of chronaxie (probably the best in the language), of the nerve impulse, where mention is made of Matthews's conclusion that the nervous impulses from skin and muscle end-organs may be *qualitatively* different, and of blood reactions regulation (with a full account of the glass-electrode technique), have all been retained May we suggest for the next edition a discussion of the chemical control of the intestinal secretions?

SCIENCE IN SOVIET RUSSIA

GENERALIZATIONS are notoriously dangerous, but many people writing about Russia seem to be prepared to take the risk Mr J G CROWTHER, for example, who made a month's tour of laboratories in Leningrad and Moscow was so favourably impressed by what he saw there that he does not hesitate to write in *Science in Soviet Russia*[2] that Russia may possibly be the most powerful country in the world in twenty years' time, and that "the rest of the world will not find the spectacle of a scientifically developed and armed people of over 100,000,000 particularly comforting" For these reasons he thinks it highly important that "relations with Soviet Russia should be carefully cultivated"

Mr Crowther's account of the actual work being carried on in Russian laboratories is rather diffuse and directed to the inexpert reader Clearly, however, it is only the experts in each branch of science who could judge whether the progress is as real as his account would have it appear That the Soviet Government is making efforts to encourage the growth of science is evident from the facts recorded by Mr Crowther about the new laboratories that have been completed, or are in course of construction, and about the sums of money that have been placed at the disposal of State departments responsible for the development of the various branches of applied science The main objective at present is the fulfilment of the five years' industrial programme, and it is only natural, therefore, that the greater part of the Government's effort should be concentrated in developing new industrial and engineering works throughout the Soviet Union We learn that the heads of manufacturing concerns must not only listen to the opinions of the expert committees appointed by the Government, but must obey their orders "If they didn't, they might get the sack, or worse, if it were proved that their obstinacy had hindered the realization of the five years' plan, and hence, in the Soviet idiom, contributed to counter-revolutionary activities"

Scientists, according to Mr Crowther, are among the best paid workers in the Union, some of them receiving as much as the equivalent of £1,200 a year, if they desire it, though Mr Crowther has heard of "one important director who did not desire so much as that"! Large salaries, however, can be gained only by hard work in multiple appointments, as the salary for a single laboratory directorship is rarely over £400 a year University appointments are even less remunerative, the salary of a senior professor being about £250 a year Mr Crowther's

They arrived either in ground-glass stoppered jars or in sealed tins, and there is no reason to assume that their vitamin content had diminished appreciably during transit

As a preliminary step samples of all four fats were saponified, the unsaponifiable matter from each was dissolved in chloroform, and the chloroform solutions were submitted to a modified Carr and Price test with antimony trichloride, under conditions which have been carefully standardized in the Glaxo laboratories during three years It was found that samples Nos 1 and 3 showed no trace of blue colour sample No 2 showed a trace, which was almost unmeasurable, sample No 4 showed an amount corresponding to 1/500 of that shown by a standard cod-liver oil, and about 1/10 of that shown by average butter By a standard cod-liver oil is meant an oil of such chromogen content that 0 02 gram of the oil dissolved in chloroform and treated with the reagent in a total volume of 2 2 c cm would give in a 1/2 inch cell a reading of 10 Lovibond units on the Rosenheim-Schuster tintometer

One gram of ghee No 2 was therefore fed daily to a rat, whose reserves of vitamin A had been depleted on a diet adequate in other respects After a temporary small increase of growth, which was probably not significant, the animal rapidly lost weight, and developed marked xerophthalmia Other animals of the same litter fed 5 mg per day of an active cod-liver oil, showed definite increases in weight, and developed no signs whatever of xerophthalmia Although the test on this sample of ghee was conducted on only one animal, the colour reaction had suggested its superiority over the other three samples none the less it was found that the effect of 5 mg of cod-liver oil was markedly superior to that of two hundred times the quantity of ghee These results clearly indicate that the ghee must have been for practical purposes devoid of vitamin A, and this in turn suggests that the other three samples were at least as deficient From the description of ghee given in Ghose's paper it is clear that there must be very considerable variations in its method of manufacture Our samples were selected, we understand, as typical of those to be obtained in the open market The sample of fresh ghee examined by Ghose even if his results were confirmed by modern technique, was quite possibly not typical in its vitamin content The results given in this note limited though the investigation has been to a super- survey suggest that the problem, which is clearly of ance to Indian dietitians, needs some fuller and ollateral investigation

is I Aitchorne Miss V Hazley and Mr E L Smith M Sc co-operated in the biological and chemical work described and I would like to take the opportunity acknowledging their w

[ILLEGIBLE] PASSED THROUGH A SINUS IN THE BACK

extremely rare, and the following case ordin_

The patient a man who had had five children was admitted 192[illegible] as a case of influenza h Hospital on December 6th 1929 back and limbs headache had been having attacks of stabbing m ning in the twenty four h noon and between the shoulder was 103° I his puls rate 92 a t very severe but the last two abn rmalities was detected on exam nd had been associated with and with an ureties l stools Altogether there On January 21 c the temperature fe [illegible] four days later he had pain in th appeared in the left and a dry cough Hi temperature was 103° harged thin yellow [illegible] ser pu tion rate 30 Pl ural friction an independently of [illegible] app ar d l ow th left scapula Within about the size [illegible] of stone had [illegible] tld and the patient s general co m the dis [illegible] proving [illegible] nts four On [illegible] ar 3 d he developed [illegible] naur in the right side [illegible] at dry cough His [illegible] emperature wa 102 [illegible] She [illegible] 0 and his respiration rate 40 The under area of [illegible] I and fr tion was pr sent of the sinus in the [illegible] the r h base d veloped and sl lumbar vertebra and [illegible] At m rature of the sw admitted the point of [illegible] of fluid rec a pir n or acetone, urine [illegible] and finally th was 238 mg per [illegible] n and dr on injected into the [illegible] followed I ject extend d upwards [illegible] ral turban n of the pancreas to that of the gall bladder It gave off a small branch, which passed downwards just to the right of the vertebral column

At operation, under gas oxygen and ether anaesthesia, the gall-bladder was found to be only a small fibrous remnant but it contained one gall stone It was opened, and the stone was removed No bile escaped The pancreas was thickened, and there was much fibrosis round the gall bladder, but no other stone was felt The wound was closed with drainage Post-operative vomiting was severe, and on the third day bile began to discharge from the wound After three weeks the bile ceased to flow and after two months the patient was discharged Her general condition was excellent, and there was only a slight exudate from each sinus The resting blood sugar was down to 140 mg per 100 c cm, and the glycosuria no longer persisted One month later both sinuses had completely healed

I can find no record of a similar external biliary fistula in the literature, and should like to express my thanks to Mr M W Bulman for permission to publish the details of this case

Reviews.

PRINCIPLES OF HYDROLOGY

NEW books and papers on hydrology are calling attention to this time-honoured branch of practice Drs R G GORDON and F G THOMSON,[1] from their experience at a great English spa, set out to apply physiological principles to the known effects of external treatment by baths They are inclined to the view that the activity of medicinal waters depends a good deal on their physical properties, such as the degree of ionization, the colloidal state of their ingredients, and their radio-activity In a series of concise chapters they summarize the action of baths on the organic systems—skin, circulation, nervous system, and metabolism—showing that on physiological grounds hydrotherapy has a rational place in medical treatment This admirable survey of physiological foundations should be useful, not only for hydrologists, but for the family practitioner, who does not always realize the value of surface treatment Many forms of external treatment are actually at his disposal, in the home and at the health resort, to rectify abnormal conditions in the skin and in the peripheral and deep circulations These often play no little part in the causation of disease, especially in temperate climates and in frigo-sensitive persons The authors refer to the value of "sedative bathing" as insulating the body from external impressions," and also, when combined with manipulation, in the treatment of many paralytic and traumatic conditions This revival of an old method has produced, in their experience, encouraging results It is interesting to note that they regard the vapour bath as one of the most valuable forms of bathing, and as far too little employed at the present time

ANTIVIRUS THERAPY

IN a volume entitled *Antivirustherapie*,[2] Professor BESREDKA has given us a further exposition of his views on immunity and their practical application in the various branches of medicine The first chapter is devoted to a consideration of the nature and mode of action of antivirus An antivirus is a filterable growth-product of an organism cultivated in nutrient broth, which according to the author, is capable of exciting a specific immunity when applied to the tissues locally The usual method of preparation is to filter a broth culture which has been incubated for ten or more days, though acting on a culture by means of a bacteriophage will give a satisfactory product and in case of emergency filtration may even be dispensed with and the whole culture used after keeping it at 100° C It is rather difficult to understand exactly how these antiviruses do their work Besredka's view is that they desensitize the susceptible tissue cells which

NOTE ON A CASE OF LIPOID NEPHROSIS.

PART I.—CLINICAL AND BIOCHEMICAL.

BY

HENRY MOORE, M.D., D.Sc.,

PROFESSOR OF MEDICINE, UNIVERSITY COLLEGE, DUBLIN, PHYSICIAN TO THE MATER MISERICORDIAE HOSPITAL, AND CONSULTING PHYSICIAN, NATIONAL MATERNITY HOSPITAL, DUBLIN;

AND

W. R. O'FARRELL, L.R.C.P. AND S.I.,

PATHOLOGIST TO THE MATER MISERICORDIAE HOSPITAL, DUBLIN.

THE term nephrosis was first suggested in 1905 by Friederick Müller[1]; it is usually employed nowadays to distinguish a bilateral degenerative and mainly tubular diffuse renal lesion in contrast with nephritis, which is limited to diffuse inflammatory and proliferative kidney changes. Valuable contributions to the problem of nephrosis were made from 1913 onwards by Munk,[2] Volhard and Fahr,[3 4] Epstein,[5] Elwin,[6] and others. In 1914 a special lipoid form of nephrosis was described by Volhard and Fahr, and has since received a good deal of attention, the following characteristics being defined.

Lipoid nephrosis has an insidious onset, but some think it may follow a comparatively mild or unnoticed attack of acute nephritis; its course is chronic; there is marked albuminuria, oliguria, decreased blood protein with relative albumin-globulin increase and reversal of the normal albumin-globulin ratio, lipaemia, hypercholesterolaemia, normal renal function tests, oedema, and no retention in the blood of nitrogenous waste products. In the urine are found casts and double refractive lipoid droplets, but no erythrocytes. The blood pressure is normal, and the basal metabolic rate is frequently below the normal. With regard to the basal metabolic rate, it should be noted that most determinations in the published cases were made when the patient was oedematous, and that the increase in body weight due to water retention tends in itself to lower the rate, which would have a higher reading were the patient oedema-free.

The main lesion in lipoid nephrosis is supposed to be a degenerative one chiefly affecting the renal tubules, but its occurrence is very rare. Very few necropsy findings of pure lipoid nephrosis have been recorded, partly because the infrequency of the condition, and partly because e patients exhibiting this syndrome usually live for considerable time, or die of intercurrent infections, or progress into chronic nephritis with glomerular as well as tubular changes. Thus, sometimes the clinical syndrome of nephrosis is present, but at necropsy the changes characteristic of nephritis are found as well as those of tubular degeneration.

Generally speaking it may be said that, while we have no pathological classification of diffuse degeneration or inflammation of the kidneys which may be used clinically to predict accurately the nature of the kidney lesions, nevertheless it appears that the clinical syndrome of nephrosis does exist. It must be remembered also that the physiological unit of architecture of the kidney is in itself a complex structure, consisting of glomerulus, proximal convoluted tubule, loop of Henle, and distal convoluted tubule which empties into a collecting tubule; that this tubular system is lined by a layer of epithelial cells which are of different types in the different parts; and that between the afferent glomerular arteriole and the efferent tubular venule a double system of capillaries exists. It is reasonable to expect that if this complex secreting structure is injured in any part, its other parts may become secondarily affected, either functionally or structurally. It is thus readily realized that a diffuse renal lesion seldom follows a simple course, but that one type of lesion frequently merges into another. The view is gaining ground that, while the most obvious early kidney lesion in lipoid nephrosis is a degenerative one affecting the tubules, changes may be found also (and possibly at an early stage in the development of the disease) in the glomeruli; these glomerular changes at first may be slight, and may require special pathological methods for their demonstration. Lipoid nephrosis is regarded by some as a particular form, or development in the course, of Bright's disease, but others think that it may be primarily due to a special type of disturbance of the lipoid-protein metabolism. At any rate, its position as a *clinical* entity is doubtless established.

The work of Barker and Kirk[7] is interesting in this connexion. These authors decreased the blood proteins in dogs by repeated bleedings, but returned the corpuscles to the circulation; when the serum protein was diminished to a certain degree by this procedure oedema appeared, and its amount seemed to be more closely related to the level of the serum albumin than to that of the total serum protein. At the time of the appearance of the oedema, albumin, fat droplets, and casts appeared in the urine, and the basal metabolic rate fell; pathological study of these dogs showed definite degeneration of the renal tubules, and later, with progression of the disorder, glomerular changes. In other words, the clinical picture of nephrosis was experimentally produced.

Christian's[8] views are of importance. This investigator believes that the majority of cases of nephrosis are mixed cases in which, clinically and pathologically, there are evidences of both nephrosis and nephritis, and that as they progress they tend to lose the clinical evidences of nephrosis, and to gain the clinical features of nephritis. He seems to consider the protein loss through albuminuria of considerable significance, and points out the necessity of liberalizing the protein of the diet to replace the protein lost from the blood through the albuminuria. He believes that the source of the albuminuria is in the passage of albumin through the walls of blood vessels, most probably glomerular capillaries, because of functional changes. He considers nephrosis as simply a form of chronic nephritis, and thinks that the name should be used merely to describe a clinical syndrome, since it does not imply that a definite and single form of pathological lesion will be found in the kidney.

Report of Case.

A man, aged 34, was admitted to the Mater Misericordiae Hospital on January 10th. His weight was 151½ lb. and height 5 ft. 7 in. The previous history is irrelevant. From six months before admission he had oedema of the legs and face, and he first noticed oedema in the legs on the day after he had marched in a procession for several hours. On admission to the hospital the legs and lower part of the back were considerably oedematous, and the face was puffy and pasty pale. Albumin was abundant in the urine, which also showed hyaline and fatty casts and a few leucocytes, but no erythrocytes. The blood pressure was 170/100, and the pulse rate 70 per minute and regular; there was slight accentuation of the aortic sound at the base of the heart. *X*-ray examination by Dr. J. Geraghty revealed pyorrhoeal absorption of the alveolar borders of most teeth present, but Professor Edward Sheridan stated that, owing to recession of the gums, there was almost complete absence of pockets, and consequently only a small area of infection at the time of examination. The nose, accessory sinuses, and throat were normal (Dr. P. Dempsey). There was dullness on percussion, and diminished breath over both pulmonary bases. *X*-ray examina

magnesium sulphate and digitalis. Tinned meat, fresh salmon, codfish, albumin water, butter, and white bread formed the basis of the diet, and wholemeal bread, wheat germ, cabbages, beans, or peas were not given. These foodstuffs were fed in small amounts at frequent intervals in as palatable a form as possible.

The patient remained on this diet for four days, during which time she got rapidly worse. The ascites increased, and her condition became critical. Paracentesis abdominis was performed and 109 oz. of fluid removed.

At this point she was put on the usual "anti-beri-beri" diet used at St. Anthony Hospital, containing wholemeal bread, fresh meat, milk, eggs, cabbages, potatoes, beans, and peas. In addition, she was given 1 oz. of wheat germ daily.

Following this change her general condition gradually improved. In about three weeks she lost the cachectic look, felt comfortable, and developed a good appetite. The red blood corpuscles rose to 4 million. The oedema, however, did not disappear from the abdomen or legs, and further paracentesis was necessary on three occasions. The urine remained free from albumin.

Seven weeks after admission, since the diagnosis was still in doubt, Dr. Curtis performed a laparotomy. Nothing was found to account for the recurrent ascites. The liver, spleen, and peritoneum were normal.

Nothing further could be done for the patient in the way of dietary treatment. It became necessary to perform paracentesis about every ten days, and when I last saw her in September she was becoming exhausted by the repeated tappings, but was otherwise in fairly good shape. Some oedema persisted in the calves and over the sacrum.

It is difficult to be completely certain that the patient's condition was due to faulty diet. The very low dietary level, which is actually below that which usually leads to severe beri-beri, and the absence of other causes to account for the oedema, makes it probable that we were dealing with a nutritional condition. Except for the fact that the dropsy did not clear up on a good diet, the case was identical with famine oedema, which certainly occurs in Newfoundland, though rarely. Appleton[10] noted four cases on the Straits of Belle Isle in 1920, and an oedema occurring in ill-nourished children, not due to nephritis, and usually responding to a good diet, is recognized at St. Anthony Hospital.

The mechanism of the production of oedema in cases of famine dropsy is unknown. Some alteration in the permeability of the capillaries is presumably present, though histological evidence of local damage has not so far been obtained. The following are among the theories that have been formulated: an extreme deficiency of calcium in the blood leading to altered permeability of the vessel walls; a "nephritis without albuminuria"; damage to the endothelial linings of the vessel walls by the products of excessive endogenous protein metabolism.

It seems possible that this was a case of famine oedema in which the capillary walls were permanently damaged and unable to recover, though the patient's general condition improved under dietary treatment. It must be remarked that wheat flour carries a fair amount of protein (10 per cent.). The high protein diet without much antineuritic vitamin did not produce improvement in the oedema or the general condition, but was tried only for a few days.

Whatever the diagnosis, it seemed worth while recording an obscure dropsical condition which followed a long period on an extremely faulty diet. It is peculiar that a patient who had practically lived on dry bread for six months or longer should develop this condition rather than one of the better-known deficiency diseases.

BLOOD CHANGES FOLLOWING INJECTION OF SANOCRYSIN IN PULMONARY TUBERCULOSIS.

BY

T. A. HUGHES, M.A., M.D., M.R.C.P., D.P.H.,
LIEUTENANT-COLONEL I.M.S.,

AND

D. L. SHRIVASTAVA, D.Sc.*

(From the Department of Clinical Medicine, King Edward Medical College, Lahore.)

PRELIMINARY REPORT.

WHEN sanocrysin was first introduced for the treatment of pulmonary tuberculosis it was believed to be capable of destroying the tubercle bacilli *in vivo*, and the reaction which frequently followed its administration was attributed to the endotoxins set free. An antitoxic serum was prepared for the purpose of counteracting this reaction and was given before each injection. This, however, was soon found to be of doubtful value and fell into disuse. It is now realized that sanocrysin acts on the tissues rather than on the bacilli, but how exactly it combats the disease is not clear. The opinion has been expressed that it acts by speeding up curative processes that go on slowly in its absence.[1]

In view of the prognostic importance attached to the variations in the white blood cells in pulmonary tuberculosis it was thought that some light might be thrown on the mode of action of sanocrysin in this disease by a study of leucocytic changes that follow its injection. A neutrophilia in phthisical patients is a bad sign, while an increase in lymphocytes is a good omen, especially in early cases. Much work has been done on the significance of the monocytic response and of the monocyte-lymphocyte ratio in tuberculosis. Some increase in monocytes is common, Cunningham and Tompkins[2] having found it in 85 per cent. of cases. It is generally stated that a diminution of monocytes and an increase of lymphocytes is a sign of improvement, and that a rise in monocytes denotes progress of the infection.[3] It is interesting to note that a monocytosis to the extent of 15.5 per cent. was found by Pittaluga and Garcia[4] in infants receiving B.C.G. vaccine.

This preliminary report deals with observations made on four patients suffering from extensive chronic bilateral disease. All were febrile when resting. In No. 1 the first dose (0.5 gram) gave rise to some improvement, but the second (0.1 gram) produced a bad effect and the treatment had to be stopped. No. 2 received only one injection, which made his condition worse. The effects of two doses (0.05 gram and 0.1 gram) were observed in No. 3. There was slight but definite benefit, especially after the second injection. No. 4 improved steadily from the start; after 4 doses (0.1, 0.25, 0.35, and 0.5 gram) the fever disappeared, the weight increased, and the sputum became scanty and free from tubercle bacilli. Injections were given at intervals of four to seven days, and there were no complications except a rise of temperature on two occasions. Control experiments with 0.1 gram to 0.15 gram were made on two individuals who were free from any evidence of active tuberculosis. Blood counts were done each morning at the same hour while the subjects were fasting. On "injection" days two counts were made, one just before and one two hours after administration of the drug. This interval was chosen because it had been noticed that when reactions occurred they were most marked two to three hours after the injections. In the differential counts at least 300 cells were noted.

The daily counts showed that in both tuberculous and non-tuberculous individuals the changes in the red cells and total white cells were irregular, but there was often a steady fall for two to four days after the injections. Abrupt rises were seen on some occasions, notably in patient No. 3, who suffered from severe night sweats. They were probably caused by concentration of the blood. An increase in the monocytes took place after every injection. This was generally observed on the following day and lasted one to three days. In the non-tuberculous

OBSERVATION AND EXPERIMENT.

SIR,—The admirable philosophical article by Mr. Wilfred Trotter in the *Journal* of July 26th (p. 129) has rightly aroused considerable attention. It is not often that space is allotted to so clear an exposition of the groundwork of medicine, and I hope the discussion will continue.

I should like to comment on the last sentence of Mr. Trotter's last paragraph: "On the other hand, it is perhaps the lack of rational doctrine and a general interest in the problems of method that has made medicine the scene of so much disunited and contradictory effort, and helped to put it down from its historical position as the mother and the nurse of science." In the first leading article in the same issue the statement is made: "In this process, method—that is, the way in which facts are discovered—has an important but secondary place," and, further on, "and it may be said to have scientific value in so far as it is adapted to the material being studied and to the ends the scientist has in view." You stress the ends of science which Mr. Trotter implies but does not specifically state in his article.

The ends or purpose of medicine are to alleviate pain, prolong life, restore to health, and promote health in the individual and the community. These are practical aims, and all the sciences have passed through this phase, but as sciences they go beyond it, and make their own contribution to the sum total of knowledge—knowledge for its own sake. Geology, first concerned with quarrying and mining, was led on by the accumulation of facts—chiefly observational, but a few experimental, as instanced by Mr. Trotter—to the stratification of the rocks, the age of the earth, and to its contribution to evolution and the antiquity of man. If geology had remained only as a means of coal or gold getting it would never have reached its present status as a science, nor would any of the other sciences had they continued in their practical stage. Medicine, if it is to reach a similar status—there is no reason why it should not—must acquire, collate, and co-ordinate its facts with the object of passing beyond the practical aims of "curing" illness and soothing pain. It does not seem to matter very much whether the facts are obtained by observation or by experiment so long as they are facts—pieces of objective reality and not subjective fancies. Such facts will find their proper place somewhere and sometime in the scheme, even if at the time of discovery they have no relevance to the practical aims of medicine.

The chief question seems to be whether medicine is in the bondship of practice, whether it is a skilled art comparable to plumbing or joinery, or whether it can emerge to give its own unique contribution to abstract thought and philosophy. When it is able to do this it will have achieved its status as a science.

There is no reason why it should not reach this position, for it deals with a distinct set of phenomena in nature—the sick man; surely there is scope enough here to lead out to the widest fields of thought. Medicine would not, of course, be coextensive with anthropology, but it would be one of its chief contributory sciences. As it is, the history of medicine is one of the branches of anthropology, but modern medicine must go further and make its own contribution from its insight into the nature of man.

The absence of rational doctrine which Mr. Trotter deplores may be but a phase in the present practical stage of medicine. That this will pass is best guaranteed by the fact that medicine possesses thinkers of the calibre of Mr. Trotter.—I am, etc.,

Warrington, Aug 10th J. S. MANSON.

DIATHERMY IN GYNAECOLOGY.

SIR,—Dr. Cumberbatch's letter in the *Journal* of August 2nd (p. 194) impels me to add my confirmation to his modest reference to his and Dr. Robinson's work in this connexion. I had the privilege in 1920–21 of seeing the very successful results of their methods, almost daily, for more than a year. Since then many articles have been published in the medical press by them and others, and in Dr. Cumberbatch's book on diathermy a detailed account is given of their methods and results.

These methods have been successfully used for years past by, probably, every up-to-date electrotherapeutist in the country; yet your reviewer deplores that "in this country we have, as yet, had little success in this direction," and lauds American superiority. In this connexion an element of humour is introduced by the fact that some years ago Dr. Cumberbatch accepted an invitation from some American medical societies to give a series of lectures in America on these subjects! Is it possible that Professor Thomas Cherry may have been present at one of these lectures?

Anyone conversant with the work of the leading British electrotherapeutists will be convinced that these workers need fear no comparison with those of any other country. A prophet is not without honour save in his own country.—I am, etc.,

Southport, Aug. 6th. J. NEWTON DYSON.

LOCAL ANAESTHESIA.

SIR,—The excellent review of my book, *Practical Local Anesthesia and its Surgical Technic*, in the *Journal* of April 5th (p. 654) contains certain statements which I feel require elucidation. Thus I am said to advise the use of "adrenaline (2 to 5 drops of 1 in 1,000 solution to each cubic centimetre of novocain solution used)." The fact is that I recommend—except in certain thyroid cases—3 minims of this solution to 30 c.cm. I am also said to advocate morphine or heroin, whereas pantopon instead of heroin is recommended.

A third point relates to the statement that space is devoted to the description of surgical instruments, etc., "matters which would more appropriately be included in a work on operative surgery." I feel that the reviewer has failed to interpret my attitude toward this subject—namely, that the successful use of local anaesthesia comprehends a modified surgical technique, or "operative surgery" if you will; one cannot be taught without the other. One instance may serve as an illustration. It is simpler to anaesthetize the abdominal sympathetic nerves than the cerebro-spinal, provided that they are exposed. In my book a comparatively large amount of space has been given to a discussion of the method of gaining this exposure. This necessitates the employment of an adjustable operating table, perfect illumination, efficient retraction, and a particular type of surgical technique. While your reviewer may see no relation between these factors and the employment of local anaesthesia I am convinced that they are so interdependent that the omission by the surgical profession to employ the proper surgical technique is the cause of failure and of the former dissatisfaction with local anaesthesia in abdominal surgery. I believe also that until surgeons realize the importance of appliances and modified surgical technique (strategy) in conjunction with local anaesthesia they will continue to find the use of the latter unsatisfactory in major work.

It is my opinion that, if local anaesthesia is the method of choice in the simplest of procedures, it should likewise be the one of choice in complicated procedures, provided that the proper strategy is employed to render the latter simple. Otherwise why employ local anaesthesia at all? There is no essential difference in the removal of a small skin tumour and a large fibroid of the uterus except in the surgical technique which is required to gain exposure in the latter. Much of the so-called "operative surgery" described in my book is there described because of the fact that very many visitors to my clinic have subsequently admitted that their dissatisfaction with local anaesthesia was due largely to their failure to realize the importance of the foregoing statements.

The successful employment of local anaesthesia is a method encompassing not only its introduction, but the preparation of an opportunity for its introduction as well; this factor involves "operative surgery," often to an extent that makes this feature more important than the administration of local anaesthesia. Hence the frequent references to surgical technique in the pages of my book. I do not condemn general, spinal, or regional anaesthesia; I have only attempted to present my views as to the most simple and satisfactory manner of employing local anaesthesia.

City and County Borough of LINCOLN.

ASSISTANT SCHOOL MEDICAL OFFICER (Woman).

The Education Committee invite applications from duly qualified and registered Medical Practitioners (women) holding a Degree or Diploma in Public Health or Science for the post of Assistant School Medical Officer. Applicants must have had not less than three years' Post-graduate experience, and preference will be given to applicants who have had previous experience in School Medical Inspection and in the Testing of Eyesight. The scale salary offered is £500 per annum, rising by annual increments of £25 to a maximum of £700 p.a.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund established under the Local Government and Other Officers Superannuation Act, 1922.

The appointment will be subject to two calendar months' notice on either side, and to the approval of the Board of Education. The officer will be required to reside within the City of Lincoln, and will not be allowed to engage in private practice.

The person appointed will be required to work under the direction of the Medical Officer of Health, and to carry out such other duties as the Medical Officer of Health may from time to time direct.

List of duties and form of application will be forwarded by the undersigned on receipt of a stamped addressed foolscap envelope.

Canvassing, either directly or indirectly, is prohibited.

Education Department, Corporation Offices, Lincoln. R. C. MINTON, Director of Education.

County Palatine of Chester.

CHESHIRE COUNTY COUNCIL.

APPOINTMENT OF DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.

The Cheshire County Council invite applications by registered male Medical Practitioners who possess a Diploma or Degree in Public Health, for the appointment of Deputy County Medical Officer of Health for the County of Chester.

The salary payable will be £1,000 per annum, in addition to travelling expenses on the prescribed scale, and office accommodation and clerical assistance will be provided.

The appointment will be an established post for the purposes of the Local Government and Other Officers Superannuation Act, 1922, and the salary will be subject to the deductions prescribed by that Act.

Applications are limited to persons not exceeding 45 years of age.

Forms of application and further particulars of the appointment can be obtained from the undersigned. Applications, accompanied by three recent testimonials, to be received not later than September 8th.

Canvassing, either directly or indirectly, is prohibited.

County Offices, Northgate Street, Chester. REGINALD POTTS, Clerk of the County Council.

August 8th 1930.

Lancashire County Council.

PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL AND DARNTON HOUSE, ASHTON-UNDER-LYNE, near MANCHESTER.

APPOINTMENT OF SENIOR ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (men) for the appointment of Senior Assistant Resident Medical Officer at the above Hospital and Institution, at a salary at the rate of £200 per annum.

Candidates should be unmarried.

The appointment will, in the first instance, be for a period of six months. The successful applicant, however, will be eligible for re-appointment for a further period of six months at the end of that period.

In addition to the salary the Resident Medical Officer will be provided with the usual residential allowances.

The Hospital comprises 300 beds, and the Union 600 beds.

Applications, accompanied by copies of not more than three testimonials, should be forwarded to the County Medical Officer, Public Health Department, County Hall, Preston, not later than August 23rd. Diplomas or Courses of Instruction should be endorsed "Senior Hospital (Medical and Surgical) Appointments" or "Junior Hospital (Medical and Surgical) Appointments conducted by the Medical Officer."

Full particulars to GEORGE ETHERTON, M.D., D.P.H., Public Health Department, County Medical School, Cambria. Clerk of the County Council.

Metropolitan Borough of Saint PANCRAS.

ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the appointment of an ASSISTANT MEDICAL OFFICER in the Public Health Department.

The appointment is a whole-time one, and the officer will be required to carry out, under the supervision of the Medical Officer of Health, such duties under the Council's Maternity and Child Welfare Scheme and Tuberculosis Scheme, as may be required from time to time by the Council. Applicants must possess the D.P.H. qualification and have had adequate experience in the duties above mentioned.

The inclusive salary will be £500 per annum, rising by annual increments of £25 to £700 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1928, and the successful applicant will be required to pass a medical examination.

Applications, endorsed "Assistant Medical Officer," stating age, qualification, and previous experience, and accompanied by copies of three recent testimonials, should be forwarded to the undersigned not later than 12 noon, Wednesday, September 3rd.

Canvassing, either directly or indirectly, any member or officer of the Council, will disqualify.

By Order,
A. POWELL COKE, Town Clerk.

Town Hall, Pancras Road, N.W.1.

County Borough of Croydon.

PUBLIC ASSISTANCE DEPARTMENT.

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Council invite applications for the above appointment at their MAYDAY ROAD HOSPITAL.

The Resident Medical Staff consists of the Medical Superintendent; Assistant Medical Superintendent and Surgical Officer; Obstetrical Officer, Medical Officer; Assistant Medical Officer. The Hospital has upwards of 500 beds and offers excellent opportunities for further experience containing a variety of good clinical material.

Candidates must have held a resident Hospital appointment, and be experienced in anaesthetics. Further particulars may be obtained from the Medical Superintendent.

Salary £300 per annum, with full residential emoluments valued at £140.

Application forms may be obtained of the undersigned, and should be returned completed, together with copies of three recent testimonials, not later than the first post on Thursday, August 28th.

JOHN M. NEWNHAM, Town Clerk.

Public Assistance Offices, Mayday Road, Thornton Heath. August 1st, 1930.

Dumfries and Galloway Joint SANATORIUM BOARD.

ASSISTANT MEDICAL SUPERINTENDENT.

Applications are invited for the appointment of Assistant Medical Superintendent of (1) the Board's Sanatorium at LOCHMABEN, Dumfriesshire, and (2) an adjoining Infectious Diseases Hospital. The officer will be required to devote his whole time to the duties and not to engage in private practice. Salary £300, rising by annual increments of £25 to £400 per annum, with board, lodging, and laundry. Candidates must be regularly qualified in Medicine and Surgery.

Full particulars and forms of application may be obtained from the undersigned with whom applications (on the prescribed form) must be lodged prior to noon of Monday, August 25th.

County Buildings, Dumfries. JOHN ROBSON, Clerk of the Board.

August 7th, 1930.

City of Salford.

HOPE HOSPITAL (1,000 Beds).

RESIDENT SURGICAL OFFICER required about September 22nd. Commencing salary £400 per annum, together with board, lodging, laundry, and attendance. Candidates must have had at least two years' general or municipal hospital experience, and must produce evidence of experience in surgical operative work. Preference will be given to candidates possessing one of the higher surgical qualifications.

Further particulars may be obtained from the Medical Superintendent, Hope Hospital, Salford, Lancs. Forms of application may be obtained by forwarding stamped addressed foolscap envelope to the Medical Officer of Health, 143, Regent Road, Salford, to whom they must be returned not later than Saturday, Aug. 30th.

H. H. TOMSON, Town Clerk.

County Borough of Darlington.

HEALTH VISITOR.

The Corporation invite applications for the appointment of Health Visitor.

Applicants must hold the following qualifications:

(a) the new Health Visitor's Certificate of the Royal Sanitary Institute; or
(b) the Certificate for Health Visitors prescribed by the Board of Education Regulations of 1919, or
(c) have held a post as Health Visitor approved by the Ministry of Health.

The duties are chiefly concerned with maternity and child welfare, and the successful applicant will be required to carry out such duties under the direction of the Medical Officer of Health.

The salary for the appointment (under the Corporation's scale) as at present adjusted by reference to the rise or fall in the cost of living is £172 16s., and is subject to such other conditions of such scale as are applicable, and additional allowances amounting to £11 in respect of travelling and uniform are made.

The salary is subject to a deduction of 5 per cent. under the Local Government and Other Officers Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

Applications, stating age, qualifications, and experience, must reach the Medical Officer of Health, Feethams, Darlington, not later than Monday, September 1st.

Town Clerk's Office, Darlington. H. HOPKINS, Town Clerk.

July 26th, 1930.

Lindsey County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited for the post of Assistant County Medical Officer of Health.

The person appointed will be required to act as an Assistant Tuberculosis Officer and School Medical Inspector. He will also be required to take charge of a Venereal Disease Clinic and act as Medical Officer to a Tuberculosis Hospital of 12 beds.

The appointment will be made in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930.

The salary will be at the rate of £600, rising by annual increments of £25 to £700, with an allowance for travelling on the County Council's scale.

Particulars of appointment and forms of application may be obtained from the undersigned. Applications to be received not later than August 23rd.

W. S. H. CAMPBELL, County Medical Officer of Health.

Public Health Dept., County Council Offices, Newland, Lincoln.

July 26th, 1930.

County Borough of Walsall.

MANOR HOSPITAL.

RESIDENT ASSISTANT MEDICAL OFFICERS.

Applications are invited from duly qualified ladies or gentlemen for the above appointments.

The salary of the first Assistant Medical Officer will be at the rate of £200 per annum, and the salary of the second Assistant Medical Officer at the rate of £150 per annum, together with the usual residential emoluments.

The appointments will be tenable for a period of twelve months.

The persons appointed will be required to act under the general direction of the Medical Officer, from whom particulars of the appointments may be obtained.

Applications, stating age, professional qualifications, and experience, accompanied by not more than three copies of recent testimonials, should be sent to the undersigned at once.

29, Leicester St., Walsall. C. S. FOTHERGILL, Public Assistance Officer.

August 8th, 1930.

City of Bradford.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S.

HOUSE PHYSICIANS and HOUSE SURGEONS required.

Salary in each case, £200 per annum, with board and lodging.

These appointments are for six months, renewable for a further period of six months.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to him not later than August 23rd.

Town Hall, Bradford. N. L. FLEMING, Town Clerk.

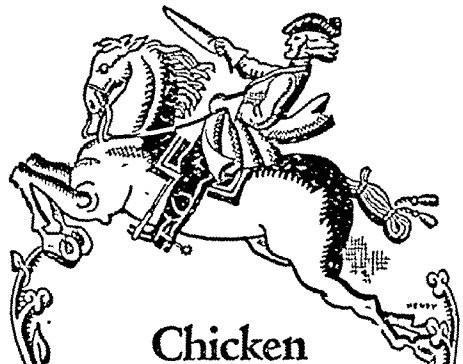
Domen Belts

Experienced Fitters.

Private Fitting Rooms.

System II.



BELT FOR GENERAL SUPPORT.

Pre-eminently useful after confinement, affording the most effectual support to the internal organs, preventing pressure on the fundus of the womb.

System II should be used in all cases where the abdominal muscles need support. It also invariably gives good results in cases of enteroptosis, gastroptosis, and all similar troubles.

Do you know..

That Humanised Trufood more closely resembles breast milk than any alternative infant food available to-day? This is a fact that has been endorsed by a series of independent tests conducted by one of the most reputable research laboratories in the country.

We invite you to put your most difficult cases of infant feeding on Humanised Trufood, because of such tests it proves its superiority.

May we send you samples and literature?

TRUFOOD LIMITED, THE CREAMERIES, WRENBURY, Nr. NANTWICH, CHESHIRE

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

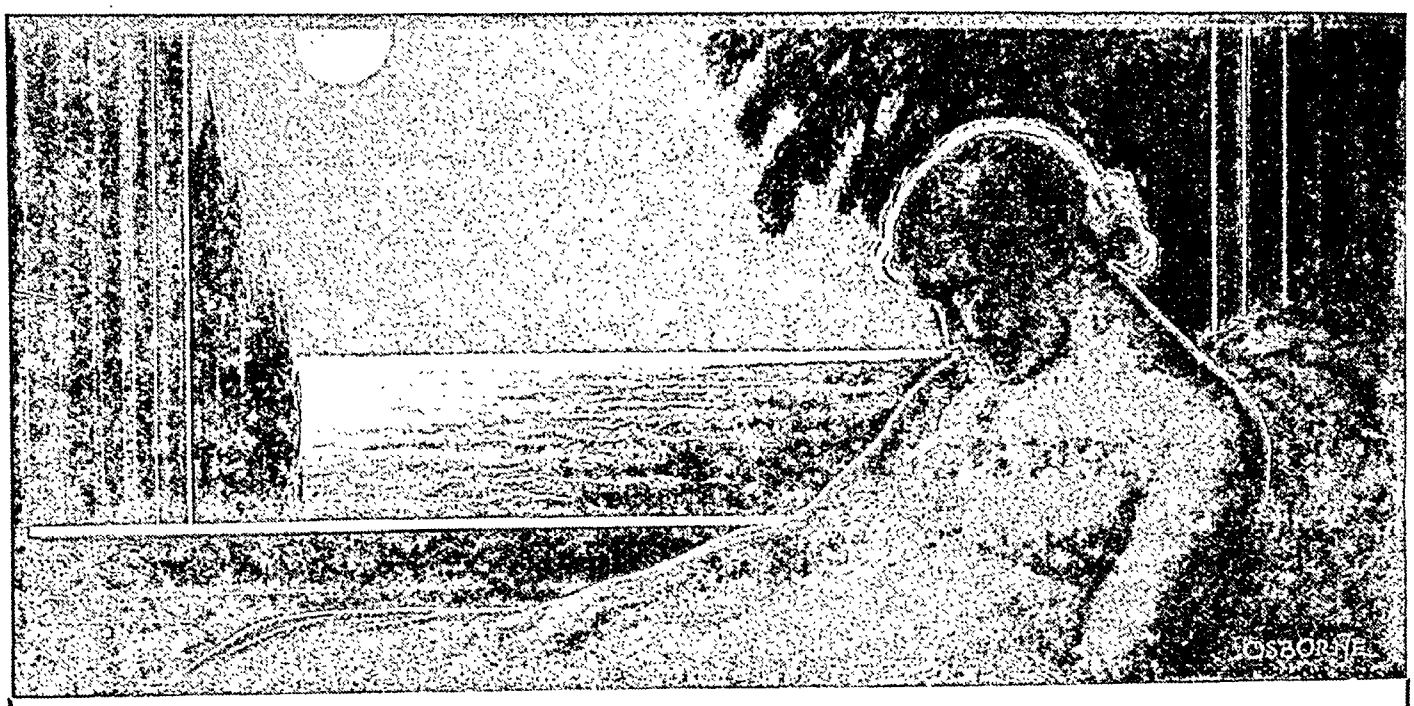
W. Borchardt (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1·4 mg. per cent. The result was similar but more striking, the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.



Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Clinical experience over a long period has demonstrated the remarkable value of

Medinal
TRADE MARK

IN

INSOMNIA

The soporific effect is rapid in onset and prolonged in action, and—in therapeutic doses—there are absolutely no toxic or carry-over effects to be feared.

In critical conditions it may be administered without danger to the patient.

The ready solubility of 'Medinal' implies quick absorption and rapid elimination.

Tablets (grs. 5 and 7½). Cachets (grs. 5 and 10). Powder.
Dose: 5-10 grains as required.

Clinical sample and literature on request from the following Overseas Depôts:

The contrast between this and the original estimate of 512 is a striking example of the remarkable effects of crossfire. It is, of course, true that the effect is greatest at the centre, that we have taken no account of absorption, and that such a distribution is unattainable in practice. The argument is, however, perfectly sound in demonstrating the value of an even distribution and the enormous increase in effective radiation which results, and incidentally it provides a substantial reason for the use of seeds by which an even distribution can most readily be obtained.

The seeds are introduced by means of a fine cannula 15 cm. in length and provided with a breech at the proximal end by which the seeds may be introduced. The seed is pushed down the cannula by means of a plunger, and is extruded at the distal end. The cannula is now withdrawn a short distance, say, 2 cm., and another seed is introduced. In this way a linear distribution of the seeds can be made with great accuracy and with no further trauma than is involved in the first introduction of the cannula. Further parallel rows of seeds can be similarly introduced, or several rows may be arranged to radiate from one puncture. The actual number of punctures in the skin required is very small, and we have usually found that for the breast six punctures will be ample, whilst for a full infiltration of the pelvis for a carcinoma of the rectum two punctures in the perineum may suffice. The resulting absolute elimination of sepsis is no small advantage of the method.

The best results are undoubtedly obtained by the introduction of large numbers of seeds, so that the total amount of radon is distributed as evenly as possible. The introduction of fifty or sixty seeds down a simple cannula is a tedious process, and I have therefore devised a magazine introducer, with a detachable magazine carrying ten seeds. The introducer is held in the left hand, and the magazine is rotated by the thumb, whilst the plunger is pushed home with the right hand. The saving of time is considerable, but perhaps even more important is the gain in precision of distribution of the seeds.

In the oesophagus this method is not applicable, and a special instrument is required. This takes the form of a long wire carrying a fine tube laterally at the distal end. A parallel wire running in guides can be pushed through this tube as a plunger. A seed is introduced into the *distal* end of the tube, which is bevelled off to a blunt needle point, and is fixed there with a little vaseline. The introducer is passed down the oesophagoscope under full visual control, and is advanced directly into the substance of the growth, the plunger is pushed home, and the seed deposited.

The Use of Seeds in Special Regions.

The application of these general principles to tumours in various regions involves in each case special considerations, and we propose to illustrate these by discussing in turn the treatment of tumours in the tongue, the breast, the rectum, and the oesophagus.

The Tongue.

The tongue is particularly adapted to the use of seeds, their introduction is such a simple matter and their [illegible] is quite unnecessary, whilst the patient is saved the annoyance of the threads which must be used [illegible] radium needles. As in the case of all tumours, [illegible] is made to infiltrate the growing edge of the [illegible] a uniform barrier of seeds. The definition of this growing edge is the most difficult part of the problem, and can only be judged after considerable experience. In this surface of growth the seeds are deposited so as to lie about 1 cm. apart, and a few additional seeds are then introduced into the tumour itself superficially to the deep growing surface. The total amount of radon used and the number of the seeds will, of course, vary with the nature of the case, but in an average case from ten to sixteen 1.5 mc. seeds will be required. They should be screened with platinum, as it is of importance that the mucous membrane of the tongue itself and of the palate should be absolutely protected from the action of beta rays.

The actual introduction of the seeds is a simple matter. Even in tumours situated at the base of the tongue it is quite easy to guide the cannula by means of a finger placed upon the ulcerated surface, and to judge of the depth at which it lies within the substance of the tongue. The needle is introduced through any convenient site, whether from the dorsal surface or from beneath the tongue, whilst in growths which extend on to the floor of the mouth the seeds may even be introduced with advantage from the neck beneath the jaw. Uniformity of arrangement so as to obtain a uniform crossfire is the chief object to be aimed at, and one should not allow oneself to be tempted to concentrate groups of seeds in the substance of the tumour where they will merely have a destructive action and produce a slough. I feel convinced that many of our failures are due to a too localized distribution of radium, and that some, at least, might have been converted into successes if a primary layer of seeds had been distributed far beyond the apparent region of the growth and not within its margins.

The course of events to be expected in a successful case is somewhat as follows. Within forty-eight hours it will be noted that the induration is diminishing, and in a week it has almost disappeared, whilst the growth is definitely smaller. At the end of two weeks the growth itself, and sometimes the adjoining mucosa, is covered by a smooth white layer of lymph, absolutely characteristic of a successful reaction. Beneath this the epithelium spreads in from the margins, and at the end of three weeks the growth has disappeared completely, the surface is healed, and only a pucker may remain. Where the growth is very large the process may take longer, and some deformity may result, but it is never in any way comparable with that produced by any form of operative removal.

The cervical lymphatic glands form one of the most difficult problems in carcinoma of the buccal cavity. It has long been recognized that in carcinoma of the tongue recurrence in the cervical lymphatics is almost invariable unless these have been removed, even where no local recurrence has taken place, and it is quite commonly bilateral. We have no doubt at all that at the present day the proper treatment of a primary carcinoma in the buccal cavity is irradiation; we cannot, however, speak with the same confidence of the cervical glands, and it still remains a question whether these should be dissected out completely, or whether we should depend on irradiation, or whether complete dissection should be followed by surface irradiation.

The method we are at present adopting is to treat the glands in precisely the same way as the primary growth, infiltrating the whole of the cervical region on the affected side with seeds, and following this up if necessary with a similar irradiation of the opposite side of the neck. In almost every case where the glands were already enlarged

OESOPHAGUS.

No.	Age.	Duration.	Character of Growth.	Dosage.	Result.
54	53	6 months	Carcinomatous stricture 12 in. from teeth.	6 × 1·5 mc.; dilated	Very marked improvement. Swallowed well for 8 months. 10 months—oesophagoscopy showed a dense stricture 1½ in. long, the walls of which were apparently formed of scirrhous carcinoma. Dilated up to 12 mm.; tube inserted. In the lumen of this tube were packed six needles containing in all 24 mg. of radium. They were left in for 4 days and then removed, the tube being left in place. Marked improvement. Lived 14 months.
55	61	4 months	Large growth 10 in. from teeth.	8 × 1·5 mc.	No improvement. 2 months, oesophagoscopy showed hard growth extending into pharynx. 8 × 1·5 seeds. Later, gastrostomy. Lived 7 months.
56	53	4 months	Carcinoma 15 in. from teeth.	8 × 1·5 mc.	Marked improvement. Swallowed well for 5 months. Recurrence at 6 months. Gastrostomy. Lived 14 months.
57	54	4 months	Carcinoma 10 in. from teeth.	7 × 1·5 mc. Tube	Marked improvement. Recurrence at 5 months. Oesophagoscopy. Infiltrating growth 2 in. above level of tube. (Post-mortem, perforation of aorta by growth.) Lived 5 months.
58	76	6 months	Carcinoma 10 in. from teeth.	8 × 1·5 mc.	No improvement. Not traced.
59	72	4 months	Carcinoma 10 in. from teeth. Condition of patient desperate.	8 × 1·5 mc.; dilated	Very marked improvement. Swallowing almost normal. At 6 months radiogram showed definite obstruction at level of hilum, but still swallowing well. Lived 9 months.
60	53	10 weeks	Obstruction above cardia, also obstruction 10 in. from teeth.	6 × 2 mc.	Marked improvement. Two months later developed pyloric obstruction. Lived 2 months.
61	49	5 weeks	Ring carcinoma 12 in. from teeth.	8 × 1·5 mc.; dilated	Very marked improvement. After 7 months cerebral embolus. Lived 7 months.
62	59	5 weeks	Large growth in anterior wall.	15 × 3 mc.; dilated	Marked improvement. Lived 10 months.
63	69	2 months	Carcinoma 2½ in. above cardia.	11 × 2 mc.; dilated	Improvement. Lived 2 months.
64	51	9 months	Growth encircling oesophagus 12 in. from teeth.	9 × 2 mc.	Marked improvement. Living after 5 months.
65	58	7 months	Fungating carcinoma 12 in. from teeth.	10 × 2 mc.; dilated	Improvement. Living after 4 months.
66	62	12 months	Large tumour in anterior wall.	10 × 2 mc.	No improvement. Not traced.
67	60	6 months	Large fixed ulcer in anterior wall. Dilatation impossible.	12 × 2 mc.	Very marked improvement. Well after 4 months.
68	61	5½ months	Round disc-like growth on posterior wall 12 in. from teeth, below this encircles wall. Dilatation impossible.	6 × 2 mc.	No improvement. Not traced.
69	49	4 months	Large growth completely obstructing lumen.	12 × 2 mc.	Improvement. Not traced.
70	55	4½ months	Fungating irregular nodular growth extending across oesophagus 13 in. from teeth.	12 × 2 mc.	Marked improvement, but intubation required later.
71	71	6 months	Large fungating growth 8 in. from teeth.	12 × 2 mc.	Marked improvement. Well after 3 months.
72	70	4 months	Carcinomatous stricture 8 in. from teeth, another much narrower just below.	12 × 2 mc., dilated	No improvement.
73	56	6 months	Carcinomatous stricture 10 in. from teeth. Nodular growth extending for about 2 in.	10 × 2 mc.	Improvement. Gastrostomy later. Lived 4 months.
74	60	4 months	Tumour 17 in. from teeth bulging into oesophagus from left side. Condition of patient desperate.	8 × 1.5 mc.	Very marked improvement. 6 weeks later swallowing normal. X-ray, apparently normal oesophagus. Swallowing normal for 9 months. Then recurrence of dysphagia. Oesophagoscopy. Secondary nodules 6 in. above site of original growth. 10 × 2 seeds. Immediate improvement. (Haemorrhage.) Lived 11 months.
75	60	6 months	Fungating carcinoma at middle of oesophagus.	8 × 1·5 mc.	Marked improvement. Lived 3 months.
76	53	18 months	Fungating carcinoma 12 in. from teeth.	10 × 2 mc.	No improvement. Lived 2½ months.
77	42	8 months	Nodular carcinoma encircling oesophagus, 18 in. from teeth.	12 × 2 mc.	Marked improvement. Well after 8 months.
78	77	3 months	Carcinomatous stricture 12 in. from teeth.	12 × 2 mc.	Improvement. Lived 4 months.
79	56	4 months	Nodular carcinoma 12 in. from teeth.	12 × 2 mc.	Remarkable improvement. Swallowing normal for 8 months. Recurrence of obstruction after 8 months. Localized fungating carcinoma at same site. Radon again inserted.

VARIOUS.

No.	Age and Sex.	Duration.	Characters of Growth.	Dosage.	Result.
80	M. 60	1 year	Indurated nodular carcinoma of lesser curve of stomach extending on to posterior wall.	18 mg. radium for 6 days	Improved at first. Died after 6 weeks from peritonitis. Post mortem, tumour had disappeared and was replaced by a large chronic ulcer involving liver and pancreas.
81	F. 72	5 weeks	Nodular growth involving both lobes of thyroid, attached to skin and compressing oesophagus.	20 × 2 mc.	10 days complete disappearance of growth and of pressure symptoms. No local recurrence. Died 7 months later from secondary deposits in liver.
82	F. 58	1 month	Spontaneous fracture. Large tumour replacing neck of right femur. Sections: columnar carcinoma of intestinal type.	8 × 1·5 mc.	Size of tumour rapidly diminished, bone united. 5 months later, reappearance of tumour. 50 × 2 radon seeds. Tumour diminished in size and pain reduced. One year later leg soundly united. No local recurrence, but secondaries in spine.
83	M. 68	9 months	Large mass of carcinoma in right anterior triangle of neck extending deep to jaw. Gross sepsis.	30 × 2 mc.	Very temporary improvement. Essentially a hopeless case.
84	M. 62	1 year	Large tumour in upper part of anterior triangle of neck (L.)	31 mg. radium for 5 days	Swelling reduced in size and pain entirely disappeared. Four months later recurrence of swelling and pain.
85	F. 45	4 months	Hard ulcerated mass on posterior surface of rectum, 3 in. diameter, absolutely fixed to sacrum.	30 × 2 mc.	Rapid diminution in size of tumour, which was replaced by a firm fibrous nodule 11 months later, small local recurrence. 14 × 2 mc. Well after 16 months.

amputated the left leg at the junction of the upper and middle thirds of the tibia on June 5th, 1929. Macroscopic and microscopic examination of the blood vessels at the site of amputation showed nothing special, and the wound healed up well at first. On July 11th, when he was getting about on crutches, slightly varicose veins were noticed in the right leg. In the right foot there was good pulsation in the dorsal artery and in the posterior tibial artery behind the internal malleolus. The brachial systolic blood pressure in both arms was 125 mm. Hg. The "oscillometric index" at the left thigh (above the site of amputation) was three divisions, and that at the right thigh, and also at the right calf, was five divisions.

However, on September 25th amputation through the middle of the left thigh had to be performed because of chronic gangrenous trouble in the stump. Macroscopic examination of the amputated part revealed some periarterial "matting" about the popliteal artery, and microscopic examination showed the artery to contain some not very old thrombus. The patient had apparently, for the last month or so, followed our advice in giving up tobacco smoking altogether. By October 19th the operation wound had almost completely healed, and there were no signs of ischaemic circulation in the stump, but a sequestrum formed, which had to be removed later on. There is still slight discharge from part of the operation wound (February, 1930), though the patient can get about well on crutches.

We confess that in the third case the diagnosis of the exact nature of the condition remains uncertain. The changes in the popliteal artery hardly afforded sufficient explanation, and an ulcus cruris must be very rare indeed as the sole or main symptom of thrombo-angiitis obliterans. The supposition that the large leg ulcer was of the ordinary kind, though without obvious varicose veins, in an individual with very poor local tissue resistance against trauma and pathogenic microbes of low-grade virulence, seemed hardly tenable for the present case. In this connexion we searched especially for any sign, however slight, of congenital haemolytic jaundice (anaemia), but with negative results.*

Remarks.

One of us (F. P. W.) has formerly seen various cases of intermittent claudication of lower extremities in English (non-Hebrew) subjects, some of them medical practitioners, but, so far as he could judge, they were mostly due to arterio-sclerosis (atheroma) of large arteries. He believes that such cases seldom progress to actual gangrene, or die of the disease in question, but in one case a post-mortem examination (after death from another disease) was made by the expressed wish of the patient, and old advanced atheroma of the abdominal aorta and iliac arteries was discovered.† Syphilitic arterial disease is certainly very rarely the cause of symptoms resembling thrombo-angiitis obliterans.‡

Recently, at other London hospitals, Dr. Weber has been given the opportunity of seeing examples of apparently true thrombo-angiitis obliterans in men without any Hebrew ancestry; in one man amputation was necessary, and in another gangrene occurred, followed by death.§ A probably arterio-sclerotic case was that of a doctor who, in 1912, when 49 or 50 years old, suffered from severe ischaemic symptoms in the left leg. Dr. Weber saw him first in 1913. He recovered sufficiently to do very active local work during the war, but developed angina pectoris in 1922. From 1924 he had symptoms of occlusion of various blood vessels. The attacks of angina pectoris continued, and he died with gangrene of the right leg in December, 1926, having refused amputation.

It seems as if intermittent claudication from arterio-sclerosis (atheroma) is almost as much confined to males as is thrombo-angiitis obliterans, and in both classes nicotine is usually a prominent item in the past history. In this connexion one must remember the extreme rarity of nicotine abuse among Jewish women of the poorer classes; but it has even been suggested that the female sex factor bestows constitutional immunity from thrombo-angiitis obliterans. Cardiac symptoms (slight angina pectoris, etc.) are probably more likely to be associated with intermittent claudication of the lower extremities when the latter is due to arterio-sclerotic changes than when it is due to thrombo-angiitis obliterans. Indeed, in cases of intermittent claudication in lower extremities, due either to arterio-sclerotic changes or to thrombo-angiitis obliterans, the supervention of angina pectoris or coronary artery symptoms (in cases known to Dr. Parkes Weber) suggests that the intermittent claudication is caused by arterio-sclerosis (atheroma)—alone or superadded to thrombo-angiitis obliterans.

* On the occurrence of chronic leg ulcers in cases of congenital haemolytic jaundice, see F. P. Weber, *Practitioner*, 1920, cxxiv, p. 392; Gänssler, *Klin. Woch.*, 1920, ix, p. 1208; *Deut. Arch. f. Klin. Med.*, 1925, clvi, p. 22.

† In this case there had likewise been cutaneous xanthoma, and it is referred to at some length by F. Parkes Weber, *Cutaneous Xanthoma*, etc., p. 14. 1924. London: H. K. Lewis and Co.

‡ Cf. A. S. Warthin, Syphilis of the Medium and Smaller Arteries, *New York Med. Journ.*, 1922, vol. 115, p. 69

§ In this case, however, the subsequent microscopical examination (Professor R. Donaldson) revealed atherosclerosis as the arterial disease.

PERNICIOUS ANAEMIA AND BLOOD TRANSFUSION.

BY

CHARLES S. D. DON, M.D.ABERD., M.R.C.P.LOND.,

HONORARY ASSISTANT PHYSICIAN, SALFORD ROYAL HOSPITAL.

THE introduction of liver treatment for pernicious anaemia by Minot and Murphy completely altered the outlook in what was usually a fatal disease. Further research, stimulated by Castle's[1] work, by Sturgis, Isaacs, and Sharp,[2] and later by Wilkinson[3] and by Conner,[4] has demonstrated the value of hog's stomach in the treatment of this disease. More recently Renshaw[5] published a case which relapsed on liver and which responded to hog's stomach (ventriculin).

There is a real danger, therefore, that the older methods of treatment may be relegated too much to the background. I have encountered cases that did not respond well to liver treatment, and in many of these the giving of arsenic and a blood transfusion has been largely responsible for tiding the patient over a dangerous period.

The most important point in giving a blood transfusion is correct grouping of the donor. I have sometimes had a little difficulty with Group III serum, as occasionally the clumping is slow and not very definite. In contrast, if clumping occurs in Group II serum, it is usually quick and leaves no room for doubt. It is a wise precaution to confirm all Group IV donors by using also a diagnostic Group IV serum. Brines[6] recently stated that since adopting this as a routine measure no error in blood grouping has been detected in his laboratory during the past six years. While serious reactions rarely occur with Group IV donors, in my own experience fewer reactions occur when the donor is of the same group as the patient, but, although I prefer patient and donor to be of the same group, I never hesitate to use a Group IV donor, no matter to which group the recipient belongs.

In pernicious anaemia the giving of unsuitable blood is a very serious matter, because, even if the transfusion is stopped at the first sign of restlessness, backache, or dyspnoea, death may follow if the patient is very anaemic. Some time ago I was asked to do a transfusion on a patient with a very low red cell count. As he belonged to Group I—the universal recipient—no care was taken in selecting a donor. After about 40 c.cm. of blood had been given he became restless, and said that the blood was too strong for him. The transfusion was stopped, but the patient died eight hours later. He was grouped again before he died, and was undoubtedly a Group I, unless the particular tubes of serums used were at fault, which is unlikely.

Unmodified blood was used in all the transfusions referred to in this paper, the Louis Jubé syringe being employed. This instrument was demonstrated to me by Dr. Skinner of Sheffield, who described it in the *British Medical Journal*[7]; since then I have done over a hundred transfusions with it, and I regard it as the most convenient method when a transfusion of 500 c.cm. or less is given. Above 500 c.cm. it is sometimes inclined to clot, but fortunately this is noticed early, and the transfusion can be discontinued. Reactions following the use of untreated blood are said by Brines[6] to be far fewer and less severe than when citrated blood is used.

I wish to record here an unusual reaction which occurred when using a Group IV donor; the patient, who belonged to Group II, was suffering from pernicious anaemia. At

LEARMONTH J R. The sympathetic nervous system 522
LEATHES J B. Harveian Oration on the birth of chemical biology 671 (O)

I have been told by many that a blood transfusion should not be given to a patient with pernicious anaemia who is running a high temperature, but I have repeatedly given 500 c.cm. of blood to patients with a temperature of 102° F., and so far I have not had a severe reaction either in cases where both donor and recipient were of the same group, or where the donor belonged to Group IV and the patient was of another group.

In most cases of pernicious anaemia, and in all cases where patients have a temperature, I give liquor arsenicalis by the mouth. In three non-febrile cases which were being treated with liver extract, one showed no improvement and the other two only very slow improvement until arsenic was given, when a prompt and rapid increase in the red blood cells took place. In each case a different firm's liver extract was used.

The case of a patient who was kept for thirty-six days on liver extract alone without showing improvement, and who made rapid progress on arsenic, will suffice to emphasize this.

CASE IV.

A man, aged 37, was admitted on November 23rd, 1928. Red blood cells were 1,600,000 per c.mm.; haemoglobin 36 per cent. He was put on liver extract in amounts equivalent to half a pound of whole liver daily without other treatment. The succeeding counts were as follows:

December 4th: Red blood cells 1,620,000 per c.mm.; haemoglobin 37 per cent.
December 15th: Red blood cells 1,650,000 per c.mm.
December 21st: Red blood cells 1,520,000 per c.mm.
December 29th: Red blood cells 1,340,000 per c.mm.

On December 29th liquor arsenicalis was prescribed in increasing doses, and on January 14th the red blood cell count was 3,370,000 per c.mm.

In the concluding paragraph, referring to liver extract, the report[8] of the Committee on Pernicious Anaemia of the Harvard Medical School states:

"Because one lot of a product has been effective it does not prove that subsequent lots will be satisfactory, as the experience of the committee under the best conditions at one time demonstrated."

Since treating the case just mentioned I have advised patients that, although they may alternate whole liver with liver extracts, on no account must the whole liver be stopped. I always double the dose of extract; if the patient is receiving whole liver in quarter-pound portions, when substituting an extract I prescribe the equivalent to half a pound. This is not a needless precaution, as I have had relapses in patients who said that they had tired of whole liver and had relied entirely on the equivalent amount of liver as extract. It is possible, of course, that these relapses might have occurred even if they had been taking whole liver, but this is doubtful.

The following case will indicate the undoubted superiority of whole liver over liver extract, at any rate in this particular patient.

CASE V.

A man, aged 29, was treated in hospital for pernicious anaemia, and discharged on September 25th, 1929, with a red blood cell count of 3,000,000 per c.mm. He took one and a half pounds of lightly cooked whole liver per week until the beginning of May, 1930, when he tired of liver and began taking liver extract in amounts equivalent to two and a quarter pounds of whole liver per week. During the time he was on whole liver he felt as well as he ever did; in addition to returning to work he was able to play games. From the middle of May, 1930, two weeks after he had substituted liver extract for whole liver, his appetite began to fail, and increasing weakness and anaemia was noticed. At the beginning of June, 1930, he stopped the extract and tried to take whole liver again, but his lack of appetite prevented him from eating much of it during the ensuing week. He was admitted to hospital on June 10th with a temperature of 100.2° F. and a red cell count of 1,040,000 per c.mm.

He was put on whole liver, half a pound a day, and arsenic, without, it must be admitted, very rapid improvement, and two transfusions were given in the course of the next two weeks before the temperature came down and real improvement set in.

Conclusions.

1. Severe cases of pernicious anaemia with a high temperature either do not respond to liver treatment or they respond very slowly.

2. Severe cases with a temperature often respond well to a blood transfusion, and in some cases it is probably a life-saving measure.

3. Improvement takes place quicker if arsenic is prescribed for cases of pernicious anaemia which are under liver treatment.

4. It is safer not to rely entirely on liver extracts. Whole liver should always be included in the diet in every case of pernicious anaemia.

ACUTE LYMPHOCYTIC LEUKAEMIA.

RECOVERY AFTER INTRAMUSCULAR INJECTIONS OF HOG SPLEEN.

BY

RAYMOND M. PEARCE, M.B., CH.B.,

MANCHESTER.

LYMPHOCYTIC leukaemia is such a rapidly fatal disease that the following account of a recovery may be of interest. In publishing it I wish to point out that I do so merely in the hope of stimulating the interest of others to try the treatment. The suggestion of using spleen extract was put forward on the grounds of the connexion in the etiology and the pathology of the disease and the imperfectly understood functions of the spleen. Workers with more material at their disposal might experiment with further cases and draw their own conclusions from their results.

A girl, aged 8, was brought to the surgery on February 1st, 1930. Her mother complained that she looked pale and tired. On examination no physical signs could be discovered to account for the child's loss of interest and energy, but there appeared to be slight anaemia. She was put on a simple iron mixture, and was seen at intervals of four or five days.

On February 19th her condition appeared to have become suddenly much worse; she was therefore ordered to bed. On the following day the degree of anaemia was found to be much more severe, and a loud systolic murmur was heard over the whole cardiac area, being loudest in the recumbent position. There was visible pulsation of the carotid arteries. The spleen could not be felt, but the liver was enlarged to one inch below the costal margin. The child had had three attacks of epistaxis, and had vomited that morning.

A blood count made on the following day was: haemoglobin 24 per cent.; red cells 1,940,000 per c.mm.; leucocytes 6,100; and colour index 0.63. The differential count was: polymorphonuclear neutrophils 40 per cent.; polymorphonuclear eosinophils 0.5 per cent.; lymphocytes 57.5 per cent.; large mononuclears 1 per cent.; and neutrophil myelocytes 1 per cent. There was great variation in the size and shape of the red cells. Punctate basophilia was prominent, and nucleated red cells were present.

The child continued to get rapidly worse. She was removed to hospital for further investigation, and a blood count made on March 3rd—that is, only twelve days after the first count—showed the following alarming progress of the disease: haemoglobin 12 per cent.; red cells 856,000 per c.mm.; leucocytes 9,600; and colour index 0.7. The differential count now was: polymorphonuclear neutrophils 7.2 per cent.; lymphocytes 87.2 per cent.; and large mononuclears 1.6 per cent. The red cells showed a great deal of change in the form of anisocytosis and poikylocytosis, polychromaxia, and punctate basophilia. Normoblasts and megaloblasts were now present in percentages of 6.4 and 0.8 respectively. Blood platelets were scanty.

On examination the spleen was found to be still not enlarged, and there was no discoverable enlargement of the lymphatic glands. She was obviously extremely ill, of a pale, yellowish waxy colour, with oedema of ankles and legs; a moderate pyrexia was present. Repeated attempts were made to administer liver extract by the mouth, and a small amount was taken, but it was vomited.

On March 7th the child was too ill to take any notice of anything, and entirely refused food. The next day it was decided to try the intramuscular injection of hog spleen and liver extract alternately. The injections were made into the gluteus medius muscle, and 5 c.cm. of a 40 per cent. albumin-free solution of hog spleen was given. Two days later 1 c.cm. of a 20 per cent. solution

MACFIE, J D Report on Winsley Sanatorium 157

Whether or not the mind or spirit was a mere function of the brain was a question for metaphysicians; what was pertinent was the fact that a particular mind might function well or ill apart from any change in bodily structure. The acknowledgement that organic disease might produce results analogous to the neuroses did not prove that a neurosis could not exist apart from organic disease. It might be that in future years pathologists might be able to demonstrate definite structural changes peculiar to the neuroses, but these would be the result of, and not the cause of, the ailment. As R. G. Gordon had pointed out, habits of thought or behaviour might be revealed in patterns of the neuronic cells. The practical point was that the neuroses could only be understood and treated if they were approached as diseases of the mind. This devotion to the theory of the organic origin of the neurosis had unfortunate consequences; such patients were subjected to every possible refinement of physical examination—a matter of much waste of time and energy. The radiographer, biochemist, pathologist, and surgeon were all called in to aid. Knowledge of the limits of the normal was so incomplete that as a rule this exhaustive examination revealed something amiss, and treatment could be directed to its cure; this might be successful, but the patient remained ill! In this way sound methods fell into disrepute, and unsound ones gained spurious reputation.

When all investigations had been made, and all treatment had failed, a diagnosis of neurosis might be made by a process of exclusion; but, fortunately, there was a better way. The history of the patient was of primary importance. Unless a patient had a psychogenic history, a diagnosis of neurosis should be avoided, for nobody became neurotic suddenly with no previous history pointing to this type of disorder. Again, the neuroses had positive signs as well as merely negative ones. To take one instance only, in a case of hemiplegia the observer should place his hands under the patient's heels and asked him to raise each in turn. If the paralysis was due to organic disease the paralysed limb would lie limp on the hand, but if it was a case of hysterical hemiplegia the paralysed limb would not only fail to be raised, but the heel would be felt to be pressed strongly down. All sick persons might usefully be divided into three primary classes: those suffering from organic disease which was the cause of all their symptoms, the effect on the mind being entirely secondary; those suffering from an organic disease and a neurosis, when either disease might be cured without material amelioration of the other; and those suffering from a neurosis alone. If this possibility of a neurosis, either alone or associated with other disease, was kept in mind, many a baffling problem would be resolved, many a mistake would be prevented, and the physician would be reminded of the great importance of using good suggestions and avoiding bad ones.

The examination of any patient who might be neurotic must be carried out with more than ordinary care. A complete physical examination was necessary, since there was no natural law which shielded a neurotic from cancer or any other illness, and an apparent neurosis might be the earliest symptom of pulmonary tuberculosis or of arteriosclerosis. In addition, the physical examination gave the opportunity of gaining the patient's confidence, an essential condition of success. When a diagnosis of neurosis had been made, the origin of the condition must be sought; this would require exemplary patience, a wide knowledge of humanity, and familiarity with psychological principles and methods, including psycho-analytic procedure and hypnotism. The time necessary for discovery might range from a single interview to a series extending over a year. The simplest case, which was encountered every week, was the patient who had a phobia that some symptom portended serious disease; if he could be assured that the symptom was of no importance he was cured. At the other end of the scale was the patient who required an entire re-education and readjustment. It might happen, as in other branches of medicine, that no final cure could be effected, but it was rare indeed that the condition could not be ameliorated, and in such cases a real service was given in that the patient was prevented from wasting his money and time, as well as that of others, by flitting from doctor to doctor, and to every variety of cult or patent remedy. Moreover, the credit of the profession was preserved.

The recovery of the neurotic patient was very largely bound up with the discovery of the origin of his neurosis. Whether or not the origin was detected, treatment would be directed towards readjusting and re-educating the patient. Use might have to be made of "suggestion," with or without hypnosis; this powerful remedy was used, consciously or unconsciously, by every doctor with every patient, yet it was apparently despised by a large section of the profession. While affecting to ignore it, there was no hesitation in ascribing to its use all the apparent cures of the quacks and miracle workers. Was it not time that the uses of this most effective agent were scientifically examined?

Dr. Pridham then cited a few illustrative cases.

A girl, aged 20, suffered from a spasmodic jerk which occurred on slight stimulus; after an attack of influenza the spasm became so marked that she was unable to return to work. After two or three interviews Dr. Pridham ascertained that she was unable to get on with her employers, who were three maiden ladies of peculiar temperament; these ladies were relations, and the patient's parents were averse to her leaving them. He interviewed the parents and the girl was allowed to change her employment; the spasm disappeared, and though he took steps to elicit a recurrence, by giving her a slight fright at the next interview, there was no such result.

This case of hysteria or conversion neurosis served as an example of the "flight into sickness" by which such patients resolved their difficulties. The situation was explained to the parents, and now, some seven years later, there had been no recurrence of the hysterical symptoms. Another well-known instance of this method of meeting troubles was the case of the soldier suffering from hysterical paraplegia. The paralysis solved the dreadful problem of the intense desire to flee from danger, and the equally intense desire not to disgrace himself or his regiment.

A woman, aged 30, was sent from an adjoining county suffering from "colitis"; she had been in bed for many weeks with a trained nurse in the house, and brought an elaborate series of charts and notes with a carefully constructed diet scheme. Dr. Pridham ascertained that there was no organic bowel disease; he found that the colitis was a term applied to excessive peristaltic action which was easily influenced by emotion; the patient's motions followed her emotions. In a week she was on ordinary diet, was up all day, and went out one evening to a dance. The treatment included the explanation of the rationale of the colitis and reassurance as to its significance, after which it was entirely ignored. It soon became evident that she required a complete re-education for her permanent cure. Unfortunately after two months she had to return to her home, which was the source of her disability, and four months later she relapsed.

A woman, aged 60, came to be cured of alcoholism; she had had previous breakdowns and had been treated in a home many years before. Suggestion treatment under light hypnosis was given on about five occasions; the patient became an abstainer and had remained so for seven years.

A married woman, aged 70, suffered from acute headaches for more than thirty years. These headaches were so acute and so unresponsive to treatment that twenty years previously she had consulted the late Sir Victor Horsley, who trephined her. Ten years later another doctor injected the occipital nerves with alcohol. Thus two competent men had been impressed with the severity of the pain, and had believed it to be due to organic disease. Dr. Pridham formed the opinion that a neurosis was present. He had been sent for one day, and had found the patient in bed in acute agony; she had lost self-control, and begged to be allowed to die. He applied light hypnotism, when she fell asleep in a few minutes and remained asleep for several hours. At her request further treatment was given by suggestion, and her headaches did not recur in a severe form for several years.

Dr. Pridham remarked that the last two cases were instances of treatment by light hypnosis. In the first instance it was noteworthy that as the alcoholism was cured the underlying neurosis became obvious. In conclusion, he suggested the possibility that neurosis was the correct diagnosis in many an obscure case, and that modern psychological methods could cure, or at least ameliorate, the condition of these patients. The credit of an honourable profession was very definitely involved in the way they were handled.

investigation before they can be accepted. With the enormous amount of trachomatous material at the disposal of the staff, guidance as to the treatment of this disease is of considerable interest. Treatment by chaulmoogra oil has been intensively practised, and while it is pointed out that this is not a specific agent in the treatment of trachoma, yet it possesses valuable properties, especially in the treatment of the later stages of the disease. Its advantage lies not so much in shortening the course of the affection as in the comparatively small discomfort which its administration involves. Treatment with carbon dioxide snow also has been investigated, but the method appears to be less satisfactory than the old-fashioned application of copper sulphate. Gold salts have also been employed as subconjunctival injections, and in some cases this method of treatment has had good results: one of the features of its use is its efficacy in producing a relatively clear cornea as a final result, but among the disadvantages of the treatment must be noted the considerable pain and discomfort to the patient and the cost of the drug.

THE PROFESSIONAL CLASSES AID COUNCIL.

THE Professional Classes Aid Council, upon which the British Medical Association is represented by its Treasurer, Mr. Bishop Harman, has enhanced the interest of its report for 1929-30 by publishing an address delivered last November by its president, Major Darwin, who is now succeeded in office by Lord Sankey, the present Lord Chancellor. Major Darwin recalled the fact that the members of the Professional Classes War Relief Council of 1914 were mostly amateurs in philanthropic work, and that, although anxious not to interfere with the work of other benevolent bodies, their efforts were for a long time regarded with suspicion. The first aim of the council still remained the same—namely, to see in every case whether the applicant could not be dealt with more effectively by some older professional association. But the giving of advice to applicants by a body upon which a very large number of professions was represented was not in itself sufficient. The council discovered that financial resources were necessary as well as advice in helping an applicant to earn again his living or to regulate his life, and that blind trust in the statements even of educated men and women was dangerous. It therefore added to its activities methods of searching inquiry and "bridge-building" financial grants, especially in such matters as education. Help is being given preferably to persons suffering from misfortunes which could not be foreseen and reasonably provided against. The aim of such assistance is not merely to provide ob[illegible]porary relief, but rather to enable the applicant to Buerger's own livelihood. The council has to deplore a the orga[illegible]eduction in income during the last twelve months, liferating [illegible]h is p[illegible]s hardly likely to be arrested under 1879; the co[illegible]is qu[illegible]nditions. "CHEVALIER" TAYLOR.

JOHN TAYLOR, who in the eighteenth century dubbed himself "Chevalier," was undoubtedly a quack, and according to Dr. Johnson a very ignorant one, but at that time nobody knew much of ophthalmology, and the practice of quacks probably differed little from that of duly qualified doctors of medicine. The chief difference between them was that the regular physicians knew their own want of knowledge and often refrained from meddling, while charlatans such as Taylor were deterred by no fear of failures, which they were prepared to explain away by impudent bluff. A good deal has been written about Taylor and his confreres from time to time. Hogarth has immortalized him, and a brief account of his career appeared in our pages twenty-five years ago[1] under the title of "Hogarth and Quackery." He also figured among "Some Notable Quacks" in the special issue of the *British Medical Journal* published on May 27th, 1911. Mr. S. Wood has recently (May, 1930) contributed to the *British Journal of Ophthalmology* a thirty-page illustrated paper on Taylor, containing a transcript of a manuscript believed to have been written by him, with facsimile reproductions of parts of it. This manuscript is in the Library of the Royal College of Surgeons of England. At the time when Taylor flourished ophthalmic surgery did not go beyond couching for cataract, some plastic operations on the eyelids, and possibly some attention to the lacrymal ducts. Conjunctivitis was also more or less successfully treated. Quack as he was, Taylor became eye surgeon to George the Second, but he left England and died at Prague. His "Life" written ostensibly by his son (who did not formally disclaim the authorship) was a scurrilous publication, by no means creditable to the author or the subject, but according to Mr. Wood the best account of Taylor is to be found in a paper by Mr. George Coats in the *Royal Ophthalmic Hospital Reports* for 1915. Mr. Wood defends Taylor from the accusation of being a mere quack, and credits him with a liberal education in general medicine and a special study of ophthalmology, but all contemporary authorities seem to have been agreed that he was uneducated and ignorant, and the extant account of his self-advertising lectures do not support a claim to culture. Mr. Wood rather gives away his case in defence of Taylor when he admits that "his conceit bordered on the pathological, and on reading his *Travels and Adventures* one is left with a feeling of disgust that a man of his ability could be so childish." Probably he did some good in the world and less harm than his contemporary, "Spot" Ward, for Taylor did not administer irritant poisons as did Ward in his blue, red, and purple antimonial pills, which were believed to have proved fatal in many cases. But a claim to be better than Ward (the statue of the latter in the House of the Society of Arts notwithstanding) is not a claim to excellence.

THE MEDICAL RESEARCH COUNCIL AND ERGOT STANDARDIZATION.

THE Medical Research Council has requested us to make public the following official statement. "The attention of the Medical Research Council (Great Britain) has been drawn to a misleading advertisement, involving misuse of their name, which has been given currency on the American continent in respect of a preparation of ergotamine tartrate known as Gynergen 'Sandoz.' This advertisement states that 'the Pharmaceutical Society of Great Britain, after consultation with the Medical Research Council, adopted Gynergen as the standard for ergot, thus making it the acknowledged leader in this field.' This statement is not true. The Medical Research Council desire to make it plain that they never at any time concurred in, or were consulted about, the adoption of this preparation as a standard. The suggestion made with reference to the Council is therefore entirely without foundation. Further, the current official publications of the Pharmaceutical Society of Great Britain state expressly that for ergot 'the standard is a sample of ergotoxine phosphate which is kept in the dark *in vacuo* over phosphorus pentoxide.' The adoption by the society of this standard, in place of a sample of ergotamine tartrate, was also announced three years ago in a paper by Burn and Ellis (*Pharmaceutical Journal*, 1927, cxviii, p. 384), which constituted a report to the chairman of the International Conference on the Biological Standardization of Certain Remedies."

should not be in the proximity of a lift-shaft or staircase-well, or near an intake or outlet of a general duct-ventilating system. In no circumstances should it communicate with a general duct-ventilating system. Preferably the store should be an isolated single-story building with independent access. Failing that, the store may be placed on the roof of a building or, if that is not feasible, in one of the higher stories in as isolated a position as possible.

The walls, floor, and ceiling of the storeroom should be fireproof and of robust construction. The door should be fireproof and of a self-closing, closely fitting type. If the storeroom forms part of a main building, a useful further precaution is a fireproof vestibule with a second fireproof door. The store should be provided with a direct vent to the outer air, preferably on the side remote from the most adjacent building. Such a vent should not normally be less than a square foot in effective area, a figure which may require to be exceeded for large stores. The vent may be protected against weather, etc., by thin, unwired glass, or other equally frail device.

The store may well be equipped with steel cabinets. If it is designed to carry unusually large stocks of films (exceeding, say, one ton), it should be divided into completely isolated fireproof compartments, each with its own vent and fireproof door. The temperature of the store should be maintained at a moderate figure. If the roof is exposed to the sun suitable thermal lagging may be necessary in hot climates. It seems certain that good quality celluloid does not ignite spontaneously at any temperature attained under ordinary room conditions. The store should be equipped with an automatic water sprinkler device. If windows are provided in a film store they are best situated in a north wall, though other considerations may be more important. Any windows immediately above the windows or vent of the storeroom should be provided with wired glass.

MENTAL TREATMENT ACT, 1930.

THE Board of Control, with the approval of the Minister of Health, has appointed a committee with the following terms of reference:

> To consider and advise what principles should be observed in the approval by the Board of Control of medical practitioners for the purposes of Sections 1 (3) and 5 (3) of the Mental Treatment Act.

The committee is constituted as follows:

Sir John Rose Bradford, P.R.C.P. (chairman).
Sir Hubert Bond, Commissioner of the Board of Control.
R. G. Gordon, M.D., F.R.C.P., British Medical Association.
G. W. B. James, M.D., D.P.M., Royal Society of Medicine.
A. Rotherham, M.B., Commissioner of the Board of Control.
J. S. B. Stopford, M.D., General Medical Council.
R. Worth, M.B., Royal Medico-Psychological Association.

With Mr. H. C. Bleakley of the Board of Control as secretary.

ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the committee thirty-four grants were made, amounting to £515. Subscriptions and donations are very urgently needed in order that the activities of the Fund may be continued and applicants given the help they need. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1. The following are particulars of a few of the cases helped.

M.R.C.S., aged 89, with wife aged 70. Has been in practice for over fifty years, but latterly, owing to increasing deafness, there was a falling off of patients. The daughter, aged 40, looks after her aged parents. The three live on a total income of £184 a year; £150 of this is contributed by the son, who is a bank cashier at a salary of £425, and has to keep himself in lodgings. Voted £40.

Widow, aged 51, of L.S.A. Her husband, who died in July, was helped by the Fund during the last two years of his life. He was also in receipt of £104 a year from another charity as he was unfit for work and in receipt of the old age pension. The widow has been left with nothing. The allowance of £104 has been discontinued as the widow is not eligible for this help, and the pension has been stopped. The widow has obtained a post as companion at a salary of £1 a week (food). Voted £26.

Widow, aged 63, of M.D. Husband died in 1929, leaving his widow quite destitute, her only support being her daughter, who is earning 48s. a week. Voted £20. Epsom College has also given a pension.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

Ireland.

Coombe Lying-in Hospital, Dublin.

IN the report for 1929 of the Coombe Lying-in Hospital, Dublin, to which a brief reference was made in the *Journal* of May 24th (p. 979), there is an interesting analysis of abnormal cases, with the treatment employed and the results. The total admissions during the year reached 1,204, with 1,080 deliveries; maternal deaths numbered only 11, and of these 10 were emergency cases. The one fatal case in which there had been previous booking of the patient was that of a woman, aged 27, who suffered from mitral stenosis, and who was admitted at the twenty-fourth week of gestation on account of profound anaemia, dyspnoea, and oedema. She improved considerably on liver extract, iron, and digitalis, but left hospital contrary to advice, and was admitted again a few weeks later in a dying condition. Puerperal sepsis was responsible for only one death among the eleven; it developed three days after bleeding from a lateral placenta praevia and delivery of a stillborn infant. In spite of glycerin drainage and a course of kharsulphan, subinvolution was marked, and the patient died on the twelfth day. Other deaths were due to accidental haemorrhage, eclampsia, ruptured uterus, shock following Caesarean section, and such extraneous conditions as cerebral haemorrhage, intestinal obstruction, and ruptured splenic artery. The members of the hospital staff are of the opinion that pelvic contraction is unduly emphasized in the training of medical students, while the signs of disproportion and their interpretation receive insufficient attention. They consider, furthermore, that unnecessary operations can only be avoided by a properly conducted trial labour. During the year there were three examples of pelvic delivery following previous Caesarean section. The first patient had a history of a stillborn child, followed by the spontaneous delivery of a living child at her second pregnancy, and Caesarean section at her third; labour was induced at the thirty-eighth week of the fourth pregnancy, and she was delivered of a living child weighing 6¾ lb. The second patient had a history of three stillbirths, followed by Caesarean section for delivery of a child weighing 9¾ lb.; in her fifth pregnancy labour was induced after the thirty-eighth week, with delivery of a 7½ lb. child. In the third case Caesarean section had been performed in a previous labour for posterior asynclitism; during the second pregnancy there was no evidence of disproportion, and she was delivered of a 7¾ lb. baby at term. The three cases give an indication of the value of individual consideration, not only of every case, but of every pregnancy of the same case. Forceps delivery was used in forty-eight labours, and it is interesting to note that among these there were only two deaths, both occurring in patients brought in as emergencies with accidental haemorrhage. Morbidity followed the use of forceps in six patients, but with recovery in every case; gonococcal infection was present in one of them, and suspected in another. Stillborn children were obtained in four cases, and five died at or soon after birth. Breech presentations occurred in 21 cases, not including twins; of these, six babies were stillborn and two macerated. Of the six stillborn, one was anencephalic, one had a prolapsed cord on admission, and the third case was sent in after repeated vaginal examinations, and was followed by morbidity in the mother after delivery. Perforation of the aftercoming head was necessary in three instances. An interesting case of chorea gravidarum was only seen at the onset of labour, and improved rapidly with recovery in ten days. The patient was treated for three days with 10 c.cm. of serum daily from patients in labour. In extern maternity work 1,432 deliveries were attended with only two maternal deaths. In the gynaecological department 304 operations were performed; *x*-ray and radium treatment were given in 16 cases and palliative treatment in 41. Three deaths occurred, one following Caesarean section for labour obstructed by round-celled sarcoma of the vagina; the other two deaths were due to peritonitis.

Hospital is expected to be able to deal with 12,000 in-patients every year. The reconstruction of St. Mary's Hospital, which in the meantime will serve with Rothwell Infirmary as a hospital for the infirm sick, is regarded as a necessary development of the hospital system of the city in the future. These proposals are considered to form a basis on which a really sound and efficient public hospital service can be built to meet the present and future needs of the city.

National Council for Maternity and Child Welfare.

Among the many activities of the constituent bodies of the National Council for Maternity and Child Welfare is the maintenance of two complete travelling exhibitions, which are concerned with many aspects of child welfare. They include a section on clothing, where model garments for infants and young children may be examined by mothers, while a food section conveys instruction about the nursery diet, the vitamin-containing foodstuffs, and the production of clean milk. There are also dental exhibits, photographs of the care and cure of crippled children, a day nursery section, and an effective chamber of horrors, illustrating a number of common dangers, and indicating how they may be avoided. The exhibition can be packed in four large hampers in half a day, and travels from town to town under the care of a lecturer. It is usually open for two or three days, sometimes for a week or two. Arrangements are made for the elder school children of the district to visit it in the mornings for special lectures and demonstrations, the afternoons being reserved for women. Lantern lectures are given wherever possible. During 1929 the exhibitions are reported to have been enthusiastically received; in one town half of the entire population—about 10,000 people—is said to have visited the exhibition hall in the course of a single week. Another constituent body of the council is the Blind Babies Department of the National Institute for the Blind. The education of the child blind from birth demands special qualities in the nurse and teacher, because there is no basis of vision on which to build up concepts. Three centres, known as the Sunshine Homes, are now provided for these infants, under the charge of a staff which trains the senses of touch and hearing, correlating them with underlying ideas. When these children are ready to pass on to a blind school, at the age of 5, they have learned "how to be blind," in the sense that they are essentially independent and self-reliant. The homes do not admit mentally defective children; they aim to be schools rather than asylums, and to give the blind child the opportunity of learning to share in the life of the community.

Wingfield Orthopaedic Hospital.

In a leading article in the *Journal* of December 12th, 1925, the second edition of Mr. G. R. Girdlestone's pamphlet, *The Care and Cure of Crippled Children*, was discussed. The scheme for the treatment of the cripples of Oxford and Bucks is well known, and there is no need to recapitulate its details. In the annual report of the Wingfield Orthopaedic Hospital, Oxon., just published, Mr. Girdlestone now records progress to the extent of an increase of patients treated in the hospital (which is the central one of the scheme) of 20 per cent., and of the out-patients attending clinics of 30 per cent. This last figure probably does not mean an increase of crippling disease, but an improved consciousness of the need of following up cases. This is likely to be the result of the reorganization of the Federation of Clinics under the name of the Berks, Bucks, and Oxon. Association for the Care of Cripples. Readers of this report are reminded that the work at the Wingfield Hospital includes vocational after-training, and that the Wingfield Workshops entered in four classes in competition at the International Exhibition of Cripples' Handicrafts held at Exeter last autumn and obtained three first awards for bootmaking and repairing, and (notably) surgical instrument making, and lamp shades. In addition, the workshops won the principal trophy of the exhibition presented by the Council for the Care of Cripples, for the best piece of work submitted by a British institution. These are encouraging facts, and show that the Oxfordshire central hospital is still leading the way. The medical and surgical staffs of the Royal Berks, Royal Bucks, and King Edward VII (Windsor) Hospitals have co-operated with the Wingfield Hospital throughout the past year. The work of the honorary surgeons is of paramount importance, but the devoted work of the honorary secretaries, committees, and helpers at the clinics has been of the greatest value, and indeed is indispensable. The average attendance at the hospital school was ninety-six. During 1929 481 operations were performed, the majority involving section of bone, and the variety and importance of the parts concerned give some idea of the value of the work done. Tendon transplantations were forty-seven, but osteotomies for bow-legs and knock-knees only twelve. It is to hoped that this last low figure means that rachitic deformities of bone are much less common than they were in the counties concerned. It is generally accepted that they are becoming rare in London, but there are wide variations of prevalence of the disease in different parts of the country.

The Leasowe Open-air Hospital for Children.

Study of the value of artificial light in the treatment of surgical tuberculosis has produced some interesting results at the Open-air Hospital for Children at Leasowe in Cheshire; a report on 224 cases was submitted to the Board of Education at the end of 1929. Except in the case of tuberculous adenitis after curetting, no evidence of any specific action of artificial light upon cases of tuberculous disease was definitely established. The value of this form of therapy seems to lie in the improvement in the general health following generalized irradiation; local irradiation with the mercury vapour lamp is considered to assist and hasten recalcification of bone during convalescence, and to promote the healing of sinuses. Experiments are being conducted to decide whether artificial light therapy has any influence on calcium retention within the body in cases where the total calcium intake and output can be estimated, since this would throw much light on the improvement in the rate of recalcification. The use of light therapy in tuberculous adenitis and peritonitis appears to shorten the duration of the stay in hospital, according to the statistics of the past two years, but deep-seated abscesses seem to be unaffected by either local or general irradiation. In the case of superficial abscesses there is some evidence that a carefully controlled dosage may induce absorption. Investigations of amyloid disease are proceeding at the hospital; the degree of retention of a dye injected intravenously is said to afford a measure of the extent of amyloid changes in the body. An attempt is being made to determine whether the alleged hastening of amyloid change under ray therapy actually occurs. During 1929 more than 200 patients were discharged from the hospital, of whom 86.6 per cent. left with the disease quiescent. Statistics of old cases show that of 110 patients discharged with quiescent lesions in 1926 94 per cent. are now known to be fit; in 1927, 132 patients were discharged, and of these 91 per cent. are now fit, while of the cases for 1928 the percentage is 95.3.

The East End Maternity Hospital.

The clinical report of the East End Maternity Hospital for the year 1929 is made up of statistical tables, the most important of which refer to the presentations and obstetrical complications met with during the period under review, and the operations that were performed in the out-patient and in-patient departments in the hospital. In the previous year 1,276 mothers had been delivered in the hospital, that being the record number in any one year; in 1929 the total reached 1,310, though the number of out-patients dropped from 788 to 610. The number of births in the hospital was 1,325; on the district it was 612. There was one case of Caesarean section for contracted pelvis, the other obstetrical operations including 58 inductions, 76 forceps deliveries, 4 versions, 15 manual extractions in cases of breech presentation, and 25 in which the placenta and membranes were removed by hand. The obstetrical

In many, a streptococcus was found, insoluble in bile, producing a green coloration on blood agar; it occasionally appeared as large diplococci varying in sugar reaction and with chains not always reacting uniformly to Gram's stain. Animal experiments were not undertaken. The only conclusion reached was that a pleomorphic streptococcus seemed to be related to the infection, though the relationship may have been very remote. None of the usual drugs had any marked effect upon the course of the disease. Various prophylactic measures were tried, most of them without success. Persons who had received prophylactic inoculations proved no more resistant than others. Some whose throats were daily painted with iodine were attacked, but regular gargling had some effect in warding off the disease. Considering its incidence, the death rate was remarkably low; six deaths were reported altogether, five of these being of persons over 60 years of age. No relationship was established between the outbreak and the prevailing climatological conditions, but there were indications that fewer cases occurred and that patients felt better in dry, frosty weather. Another matter referred to by Dr. Fyfe in his report is the organization of the national health insurance scheme, which he considers is in need of revision. From a study of panel records he thinks that the administration of the Act should be more intimately linked up with the administration of public health. If the work of the general practitioner was co-ordinated with that of the medical officer of health, their concerted efforts, in his opinion, would enable a thorough investigation of the health of the nation to be made.

The Royal Samaritan Hospital for Women, Glasgow.

Gynaecologists and others engaged in hospital work will be interested in the statistical report of the Royal Samaritan Hospital for Women, Glasgow, for 1929. This institution came into being in 1886, and ten years later was rebuilt; new wings were added in 1906 and again in 1927, and the present report represents the first account of a full year's work of the hospital since the most recent extension. The classification of the figures presented obvious difficulties, and it was not found possible to devise a strictly anatomical or pathological basis. Four main headings are therefore employed—namely, diseases restricted to one of certain regions of the genito-urinary tract; diseases affecting more than one such region; related diseases outside the genital and urinary tracts; and conditions not classified in the foregoing groups. Where the disease was restricted to a definite region a sub-classification has been employed—namely, (1) disorders of function without macroscopical changes and developmental errors; (2) conditions resulting from infection and calculi; (3) hypertrophy, hyperplasia, neoplasms, and cysts; (4) circulatory disturbances; and (5) diseases associated with pregnancy. The second main heading comprises: malformations and developmental errors; diseased conditions resulting from infection; and obstetrical and other injuries such as prolapse, displacements, fistulas, and hernias. Diseases outside the genital and urinary tracts include: primary and secondary anaemia; cardiac and pulmonary conditions; and diseases of the alimentary canal, particularly appendicitis and haemorrhoids. The number of patients dealt with was 2,841, and a detailed list is supplied of the various conditions encountered. The etiological evidence is tabulated, reference being made particularly to the association or otherwise of childbearing, developmental errors, and the incidence of new growth.

James Murray's Royal Asylum, Perth.

In 1827 there was brought into existence, in Perth, James Murray's Asylum, and subsequently it was incorporated by Royal Charter. The nominal number of available beds at present is 200. In the hundred and third annual report of this institution, for the year ended March 31st, 1930, Dr. W. D. Chambers, the physician-superintendent, states that at this date there were 181 patients on the registers of the institution, of whom 177 were resident. A number of new patients were refused admission during the year owing to lack of accommodation, but a new reception hospital, in course of erection at Gilgal, is expected to be available in a few months. In the twelve months under review 81 patients were admitted (42 men and 39 women); 70 were discharged; and 22 died. Voluntary admissions constituted 70.4 per cent. of the total admissions, male patients numbering 30 and female 27. Among the causes which were considered to have been wholly or partly responsible for the mental breakdown were adolescence in 14 cases, the climacteric in 13, and the senile or pre-senile period in 12 cases. In 15 cases the symptoms were affected by alcoholism, and in one case by addiction to morphine. There were 3 cases of epilepsy, 5 of syphilis, 4 of influenza, and 1 of encephalitis lethargica. Of those discharged, 17 certified and 20 voluntary patients had recovered, and 27 were relieved. The average age at death was 65.2 years, the death rate being 12.4 per cent. of the average daily population. In a postscript to the report Dr. Chambers refers to the fire in April which destroyed the roof of the east wing, and draws attention to the fact that much more extensive damage was prevented largely by the sound fireproof structure of the building. The loss has been assessed at approximately £2,400. It is recalled that after a previous outbreak of fire in 1837, which destroyed the roof of this same wing, the then directors rebuilt it with fireproof arches, a policy which has now proved to be most wise, since otherwise the recent disaster would have probably resulted in the destruction of the whole wing.

Correspondence.

A NATIONAL MATERNITY SERVICE.

SIR,—The interim report of the Departmental Committee on Maternal Mortality, as reviewed in the *Times* of August 6th, is a little difficult to understand, since the results of its investigations into the causes of maternal deaths and the remedies suggested seem to bear no logical relationship to each other. The one important exception is the clause urging the better teaching of obstetrics. As this, the most sensible clause, will, if carried out, not involve the expenditure of public money, or provide bureaucrats with a job, or bring glory to the politicians, it will probably be the least popular with the authorities.

The following facts are, according to the *Times*, the chief evidence on which the committee has based its conclusions. (1) That the maternal death rate is 4.3 per 1,000. This figure can scarcely be called alarming. (2) That in the United States (where the cult of health almost amounts to a disease) the maternal mortality is 8.3 per 1,000, while in France, where, one is given to understand, medical facilities are not of the high standard provided in England and Wales and the United States, the rate is only 2.5. (3) That in England and Wales since 1911–15 the rate has risen from 4 to 4.3 per 1,000. (4) That overcrowding and dirty conditions have no appreciable relation to puerperal sepsis.

In face of these findings, why does the committee recommend the establishment of a general maternity service (midwifery service would be a more accurate name for it)? Ante-natal care and asepsis have been practised on a growing scale for a number of years, yet not only have they failed to reduce the mortality rate, they have failed to prevent a slight increase.

The review of the interim report in the *Journal* of August 9th quotes none of these findings, but it does quote some other figures which may be misleading: thus 48 per cent. of maternal deaths are said to be preventable. These are classified in four groups: (1) deaths resulting from omission or inadequacy of ante-natal management; (2) deaths resulting from errors of judgement in management; (3) deaths due to lack of reasonable facilities; and (4) deaths due to negligence on the part of patients. Of these, only those in the third group might be prevented by the provision of a general midwifery service. Of 2,000 cases investigated 64 were put into this group; that is to say, only 3.2 per cent. of maternal deaths might be prevented by a general service. Since the maternal mortality rate is 4.3 per 1,000, this means that the rate would fall by less than 0.2 per 1,000, so that if each birth

She then developed neuritis and, after all the usual examinations had been made with negative results, the appendix was removed.

The association of ocular inflammation with abdominal sepsis is recognized by every ophthalmologist of experience, and it is a matter of surprise that a reviewer of a valuable work by a surgeon of world-wide reputation should be so flippant. It is quite obvious that when Dr. Watson-Williams mentions "errors of refraction" he does not mean the optical abnormality, but the symptoms associated with such errors—asthenopia and headache. The relationship between asthenopic symptoms and sinus disease was the subject of a communication made by an American rhinologist to the Oxford Ophthalmological Congress in 1929; there is little doubt that the irritation of a septic nasal sinus can give rise to ocular symptoms quite apart from any actual disease of the eyes.—I am, etc.,

Birmingham, Aug. 8th. F. Harrison Butler.

DIATHERMY IN GYNAECOLOGY.

Sir,—I have pleasure in adding my testimony to that of Dr. J. Newton Dyson, whose letter on August 16th (p. 266) confirmed the statements made by Dr. Cumberbatch in the *Journal* of August 2nd (p. 194) concerning the pioneer work undertaken by himself and Dr. Robinson in the above connexion. I studied the methods of Drs. Cumberbatch and Robinson for two years under their direct guidance and supervision. I have since continued their principles in my own practice with complete success in cases of chronic gonorrhoea, in both women and men, to our mutual satisfaction and the abiding gratitude of the patients. My medical friends, however, smile indulgently and incredulously when I tell them that, speaking from my own experience, about 90 per cent. of cases can be cured by this means alone, and that, if employed with other methods, the percentage of cures is nearer 100.—I am, etc.,

London, W 2, Aug. 18th. R. Galway Murray.

THE PERFORMANCE OF NECROPSIES BY GENERAL PRACTITIONERS.

Sir,—I heartily agree with the comments of "Rusticus" in the *Journal* of August 9th (p. 228). I suggest that, in rural districts, each coroner should appoint two or three general practitioners to do all the post-mortem work, with the help, in each case, of the medical attendant. Those appointed would quickly gain sufficient experience to form reliable opinions about the cause of death, and the medical attendants would learn enough to take up the appointments when vacancies occurred.—I am, etc.,

August 10th. A Country Doctor.

Sir,—Having had twenty-five years' experience as a country practitioner, I entirely agree with the indictment by "Rusticus" (*Journal*, August 9th, p. 228) of the present obsolete and unsatisfactory conditions under which medical men practising in rural districts are expected by coroners to carry out post-mortem examinations. There is certainly, in my opinion, urgent need for reform in the present methods, which he so justly condemns.—I am, etc.,

August 11th. Country G.P.

Obituary.

CHARLES BROOK, F.R.C.S.,

Vice-President and Consulting Surgeon, Lincoln County Hospital

We have to record with regret the death of Lieut.-Colonel Charles Brook, R.A.M.C.T., who died at his residence in Lincoln on August 10th, in his ninety-second year, he was one of the oldest medical men in the country. In a long and distinguished career he showed conspicuous ability both in civil and military spheres, and his death is profoundly mourned in Lincoln, where he was senior magistrate.

Charles Brook was born in Lincoln, and after studying for a year at the Lincoln County Hospital he entered St. Bartholomew's Hospital in 1858, where he won a scholarship and prizes for anatomy and clinical surgery; he obtained the diplomas M.R.C.S. and L.S.A. in 1861. He was then appointed house-surgeon at St. Bartholomew's, but resigned owing to the illness of his father, the late Dr. W. H. Brook, succeeding him in practice at Lincoln in 1862. Two years later he was appointed surgeon to the Lincoln County Hospital, and in 1900 he became consulting surgeon; he was elected vice-president of this institution in 1921. He was also chairman of the Lincoln Dispensary. In 1922 he was elected to the Fellowship of the Royal College of Surgeons of England as a distinguished member of twenty years' standing. His association with the Army dates from 1862, when he was commissioned assistant-surgeon to the Royal North Lincoln Militia, afterwards the 3rd Battalion of the 10th Foot (Lincoln) Regiment; he was promoted to surgeon-major in 1877, and retired in 1891. Although he was 75 at the outbreak of war in 1914 he was then appointed senior officer of the surgical staff of the 4th Northern General Hospital, retiring in May, 1918, with the rank of lieutenant-colonel.

Always an enthusiastic sportsman, Charles Brook excelled as a cricketer, a keen rider to hounds, and a good shot, able to tramp over the heather until nearly 80. He was chairman of the Lincoln Race Committee until 1926, racing himself at one time under the name of "Mr. Seabrook." His business instincts and organizing ability enabled him to render valuable services on the boards of several important local commercial organizations; and he was chairman for a time of the local Conservative Association. He was the senior city magistrate, having been appointed J.P. as long ago as 1888. For many years he was a member of the British Medical Association, being chairman of the Lincoln Division from 1924 to 1928. He is survived by a son and daughter, his wife and an elder son having predeceased him.

Lord Moynihan writes: I am so sorry to hear of dear old Charles Brook's death; he was a great figure and a fine type of cultured English gentleman, and there is surely nothing so fine as that.

Mr. George Robertson, F.R.C.S., who died at Bonar Bridge, Sutherlandshire, on August 2nd, was born at Dunfermline in 1879 and received his medical education in Edinburgh, where he obtained the diplomas L.R.C.P., L.R.C.S., and the L.R.F.P. and S.Glas. in 1900, after a distinguished career as a medical student, in which he won the Pattison bursary, the Bathgate gold medal, and the residents' prize for clinical surgery. After holding the post of resident surgeon in the gynaecological ward of the Royal Infirmary and in the Royal Maternity and Simpson Memorial Hospital, he returned to his native town and quickly built up a large practice, becoming a surgeon of considerable ability and skill. During the war Dr. Robertson served on the Eastern Front as a captain in the R.A.M.C. He became a Fellow of the Royal College of Surgeons of Edinburgh in 1918, and was appointed surgeon to the Dunfermline and West Fife Hospital. He published numerous communications on surgical subjects. Dr. Robertson was on holiday at the time of his death, which was due to a heart affection. He is survived by a widow and a daughter.

Dr. Gerald Alfred Child of Hythe, Southampton, who died on August 11th, aged 59, was the only son of the late Rev. Alfred Child, rector of Upper Clatford, Hants. He was educated at the University of Oxford and St. Thomas's Hospital Medical School, and obtained the diplomas M.R.C.S. and L.R.C.P. in 1895. He was medical officer of the Beaulieu, Dibden, and Hythe district of the New Forest Union, and also of the Hythe and Dibden Cottage Hospital. He was joint designer of the Leslie and Child ambulance, which was adopted by the War Office and extensively used during the war. The distinction of O.B.E. was conferred on him for his services, which included supervision of the work of the Hampshire Automobile Club Ambulance, which had the fine record of travelling 695,890 miles and removing 211,400 cases from hospital ships in Southampton Docks. He was also surgeon-in-charge of the West Cliff War Hospital throughout the period of hostilities. Dr. Child was a member of the Southampton Division of the British Medical Association.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DERMATITIS HERPETIFORMIS.

"F. H. R.," replying to Dr. J. E. Richmond (August 2nd, p. 200), writes: Permanent change of locality may cure, but relapses can occur if only a holiday or stay in hospital is taken. Cure has been reported from vaccines prepared from the vesicles; vaccines made from any abnormal intestinal bacteria or from any existent infective focus may help. A diet of milk and water only in an acute attack, if persevered with, has been known to cause the disease to disappear. Great benefit may result from thyroid extract, insulin, alkaline diuretic mixtures, and hexamine; ultra-violet ray treatment, general galvanization, and auto-serotherapy are also worth trial. There is no certain cure, but the measures mentioned have sometimes been successful. General treatment should aim at combating the decided neurotic and toxic forces present in this disease.

SOUR MILK.

DR. W. CAMPBELL MACKIE (Wigan), replying to "E. W. D.," suggests the use of Grade A milk acidified with lacteol tablets, which must be kept carefully corked in their tubes. Three or four are soaked and placed in a tablespoonful of the milk; they are then crushed, intimately mixed with it, and the mixture then transferred to one or two pints of milk. This is well stirred, and left at room temperature during the summer, or in winter kept at body temperature. The milk is soured in six to eight hours, and is then ready for use. Dr. Campbell Mackie advises also the administration of a preparation—"colactin"—marketed by E. H. Spicer, Watford, Herts, since this aids the establishment of *B. bulgaricus* in the large intestine.

DR. C. G SALVESEN (Tarland, Aberdeenshire) writes: In reply to "E. W. D.," who asks for advice regarding the artificial souring of milk in the *Journal* of August 9th (p. 236), I may state that this form of milk is very extensively used in the Scandinavian countries as a daily food, and is prepared as follows. The bottom of a deep plate or bowl is smeared with a teaspoonful of sour milk or cream; the dish is then filled with fresh milk and allowed to stand for 24 to 36 hours in a warm place, such as a kitchen cupboard, but not on a range. When ready a thick cream should have formed, and the milk below should be fairly firm. Eaten with a sprinkling of brown sugar and cornflakes or grape-nuts it is a delightful summer food, but is in most cases an acquired taste. A little of the top cream should be used for preparing the next supply.

"R. G." recommends the following procedure: Squeeze into a teacup the juice of half a lemon, and add to this half a teacup of warm boiled milk (blood heat) with a nut of butter. Keep in a warm place. The mixture ought to "set" in twenty-four hours. A tablespoonful of this, stirred into half a pint of hot milk and kept in a warm place, gives the supply for the next day, and so on.

ANOTHER CORRESPONDENT writes to recommend "yaghourt," which may be purchased from Boudja Manoli, 22, Great Chapel Street, Soho. The sour milk is prepared from this, and information about the method may be obtained from the suppliers.

TREATMENT OF DYSMENORRHŒA.

DR. BLANCHE HENDERSON (West Hartlepool), replying to Dr. Murray's inquiry (August 16th, p. 272), writes: I am inclined to think much might be done by encouraging the patient to believe that the pain will lessen if she will be very persevering with the following treatment: sedobrol daily, with veramon p.r.n.; also laxatives, a tonic, and postural exercises, such as raising the pelvis above the level of the thorax. If possible, the patient should remain in bed, with a hot bottle the first day. She should be encouraged to try to get her mind off the condition and to occupy herself fully.

INCOME TAX.

Expense of Purchasing a Practice.

"W. S." bought a practice in 1929 and thereby incurred certain legal and other costs as well as the expense of removing from non-professional to professional premises. Is any allowance due in respect of these expenses?

*** No; they represent the cost of acquiring and starting his practice rather than expenses incurred in carrying on the work. On the analogy of other decided cases, "W. S." has no legal claim to deduct these expenses.

LETTERS, NOTES, ETC.

HOLIDAYS FOR FACTORY GIRLS.

WE have received the following letter, signed on behalf of the Factory Girls' Country Holiday Fund by the Countess of Sandwich, Dame Mary Scharlieb, Miss Lilian Braithwaite, Sir Thomas Barlow, the Bishop of London, the Chief Rabbi, the Rev. R. F. Horton, and Mr. J. F. Green: May we again ask for your friendly co-operation in our efforts to help women workers in factories, workshops, and domestic service to obtain a restful and much-needed holiday away from the congested and noisy areas of industrial centres? It is a principle of the Factory Girls' Country Holiday Fund to ask the girls and women themselves to contribute to the expense of their holiday to the best of their ability; but if they were dependent entirely upon their own savings, necessarily small, the holiday would be quite out of the question. Through your columns we beg leave to ask the public, which has not failed us in the past, to help again those who cannot adequately help themselves. The benefit derived by these women and girls, who after a strenuous day go home to stuffy streets and crowded dwellings, is almost incalculable. The holiday means change of air, change of scene, change of interests. It infuses those who enjoy it with new life; it inspires them with new hope; it invigorates the body and refreshes the mind. The scene presented week after week at the headquarters by a crowd of tired but eager and excited girls and women ready to start off on a holiday, or by another crowd returning home, the picture of health and happiness, demonstrates the immensity of the benefits received. Those who watch it are filled with gratitude to subscribers to the Fund who by their magnanimity and generosity help to make such holidays possible. Subscriptions and donations will be thankfully received and acknowledged by the honorary treasurer, Mrs. Slater, or by Miss Canney, 75, Lamb's Conduit Street, London, W.C.1.

FOREIGN BODY IN THE VAGINA.

MR. IAN FRASER (Belfast) recalls the case of the insertion of a hairpin into a child's vagina (July 26th, p. 168), and reports the case of an unmarried girl, aged 19, who had a fetid and blood-stained vaginal discharge. He writes: Examination revealed a wooden object impacted in the vagina. It was so firmly implanted that her doctor was unable to move it; with difficulty I was able to get between the softened vaginal wall and the wooden object and extract it. It turned out to be a boy's penny top, which she had put in pointed end foremost ten days previously. During it in bed! accident—in fact, she had sat on it as a

SEVERE CEREBRAL SYMPTOMS FOLLOWING SPIROCID ADMINISTRATION.

WITH regard to an abstract in the Journal of August 16th (*Epitome*, para. 146) entitled "Severe cerebral symptoms following stovarsol administration," we have received a communication from Messrs. May and Baker, Ltd. (Battersea), pointing out that it is apparent that spirocid and not stovarsol was the preparation used in the case recorded. They add: stovarsol is a registered trade mark belonging to ourselves.

ERRATA.

WE much regret that in the *Journal* of July 26th (p. 135) a line was omitted from the article by Dr. Leonard Colebrook entitled "Infection by anaerobic streptococci in puerperal fever." The last sentence of the paragraph on the third page describing the clinical features of seventeen cases of generalized infection due to anaerobic streptococci should have been as follows: It may be noted that 5 of the 9 cases which developed suppuration gave mixed cultures from the blood, and in 3 of them a septic thrombus was found post mortem.

PROFESSOR HENRY MOORE calls our attention to the fact that in the first line of his article on lipoid nephrosis in the *Journal* of August 16th (p. 242), the name Friedrich was given as mis-spelt as Friederick.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41 of the Advertisement columns appear in the *Supplement* at page *123*.

181. Hepato-biliary Infection by Friedlander's Bacillus.

P. CARNOT, J. DUMONT, and E. LIBERT (*Paris Méd.*, May 24th, 1930, p. 479) report the case of a man, aged 44, who in 1923 had had an appendicectomy on account of crises of abdominal pain, and in 1925 a cholecystectomy for violent abdominal pain followed by jaundice. He was admitted into hospital in January, 1929, on account of rigors, temperature, pain in the right hypochondrium, biliary vomiting, and jaundice. A blood culture was negative. He was given atophan by the mouth daily for ten days, and left the hospital apparently cured, but he returned to hospital with a relapse in November. Bacteriological examination of the bile obtained by a duodenal tube showed the presence of the pneumobacillus of Friedländer, but its significance was overlooked. He recovered rapidly with intravenous injections of hexamine, was discharged, and returned for another course of injections in December. He was readmitted in January, 1930, with a severe relapse; the liver was palpable five finger-breadths below the costal margin. The blood culture on this occasion showed the presence of the bacillus of Friedländer, and culture of the bile obtained by duodenal tubage was always positive. The biological reactions of the pneumobacillus showed that it was pathogenic. In spite of the administration of atophan and an autogenous vaccine, duodenal drainage, and non-surgical drainage of the bile passages by the method of Vincent Lyon, the patient remained pyrexial till the end of February. He was discharged improved early in March at his own request, but was readmitted a few days later, and died in a few hours. Permission for a necropsy was refused. A second patient, a woman, aged 23, was seen in hospital in February, 1930, with a history of three weeks' jaundice following dyspepsia, anorexia, and obstinate constipation. The clinical examination was, generally, negative, but the bacteriological examination of the bile obtained by duodenal tubage yielded Friedländer's bacillus in pure culture, culturally identical with that obtained in the first case. This case, however, responded to simple measures, and the patient was discharged cured in a month.

182. Gangrene associated with Scarlet Fever.

D. S. SUTHERLAND (*Brit. Journ. Child. Dis.*, April–June, 1930, p. 102), after reviewing the literature and emphasizing the rarity of this condition, records two personal cases. The first patient was a Jewish boy, aged 4½ years, who on the eighteenth day of a mild attack of scarlet fever developed gangrene of the left leg. A definite line of demarcation appeared just above the knee in the fourth week. A diagnosis of embolic gangrene was made, and amputation was performed a fortnight later, recovery ensuing. No evidence of thrombosis or embolism, however, was found in the amputated leg. The second case of gangrene occurred in a boy, aged 4, suffering from post-scarlatinal nephritis and otitis media, who developed purpura fulminans on the thirty-sixth day of disease and died on the forty-second. There was no necropsy.

183. Leprosy and Malignant Growths.

J. J. PUENTE and M. I. QUIROGA (*Rev. Méd. Latino-Americana*, February, 1930, p. 671) illustrate the rarity of the coexistence of leprosy and cancer by the following statistics. Among 2,337 deaths in the Norwegian leper hospitals there were only 19 cases of cancer, in Rejkjavik 2 among 105, in the Philippines 5 among 300, and in Portugal only 1 among 2,000. Puente and Quiroga now record 4 cases of cancer which occurred among 700 cases of leprosy, a proportion of 5.6 per 1,000. The first patient was a man, aged 62, suffering from the purely nervous form of leprosy, who had an epithelioma of the cheek. The second was a man, aged 37, with the mixed form of leprosy and a destructive epithelioma of the nose. The third was a man, aged 60, who had the mixed form of leprosy; epithelioma of the gall-bladder was found at the necropsy. The fourth patient was a woman, aged 23, with macular leprosy and scirrhous cancer of the breast.

184. Prevention of Prostatic Hypertrophy.

E. G. BALLINGER, O. F. ELDER, and H. P. MCDONALD (*Urol., and Cut. Rev.*, June, 1930, p. 374) state that benign hypertrophy of the prostate is usually due to hyperplastic changes which are probably caused by a mildly irritating intrastatic substance. They claim that massage of the prostate to express the stagnant secretion containing the toxic agent from the glandular structure of the organ may prevent hypertrophy and urinary obstruction if employed at the beginning of obstructive changes. Patients suffering from oedematous prostates often receive as prompt relief from prostatic massage as do those with definite prostatitis. Before a course of massage is prescribed, however, care should be taken to exclude a median fibrous bar or contraction of the vesical neck, carcinoma, tuberculosis, and calculus of the prostate.

Therapeutics.

185. Oxygen in Coronary Thrombosis.

R. L. LEVY and A. L. BARACH (*Jour. Amer. Med. Assoc.*, May 3rd, 1930, p. 1363) believe that anoxaemia plays a critical part in determining the outcome after the incidence of coronary thrombosis. By the use of an oxygen tent a concentration of 45 to 50 per cent. of this gas may be obtained. The authors suggest that such treatment may maintain an adequate circulation until the heart has had an opportunity to recover from its acute functional disturbance in cases when the injury is not so severe that such recovery is impossible. They describe a case in detail in which relief was given in this way for four days; the tent was then removed, but cyanosis returned and Cheyne-Stokes breathing recurred. The patient continued to become alarmingly worse and the tent was replaced, with prompt relief. On the ninth day after the onset of the illness, and after approximately seven days in an atmosphere of 45 per cent. oxygen, the tent was removed finally, without any untoward effect on the patient, who improved from that time slowly but continuously. The authors state that in other cases also subjective improvement was similarly brought about in from one to three hours after the administration of oxygen was begun. Relief was given to the respiratory embarrassment and restlessness; the cyanosis was diminished or abolished; the respiratory rate was slowed and the Cheyne-Stokes breathing, if present, tended to disappear; the heart became slower, the cardiac sounds grew stronger, and the volume of the pulse improved.

186. Sodium Thiosulphate in Cyanide Poisoning.

M. SCHMIDT (*Ugeskrift for Laeger*, June 5th, 1930, p. 548) draws attention to the markedly reducing properties of sodium thiosulphate which has recently been employed in poisonings of many kinds. Given in a 10 per cent. solution by intravenous injection, it has been tried in cases of poisoning by salvarsan and sanocrysin. In the most recent textbooks on toxicology it is recommended with no great show of enthusiasm in potassium cyanide poisoning, in doses of about 0.1 gram, a 1 or 0.5 per cent. solution being prescribed by subcutaneous or intravenous injection. The author suggests that in the light of the dramatic case recorded by Feyerabend (*Klin. Woch.*, 1928), and of the equally dramatic case he records in the present paper, the uncertain favour this remedy has hitherto enjoyed is attributable to the timid dosage given in the past. His own case was that of a workman, aged 34, who made a solution of potassium cyanide, obtained for photographic purposes, and drank a little of it. A minute later he lost consciousness and was bathed in cold sweat. Consciousness was still completely lost when he was first seen by a medical man some twenty minutes later. His respiration was heaving, there was froth about his mouth, the eyes were wide open, and there was no corneal reflex, but the pupils were widely dilated. There were no muscular twitchings, the limbs were completely flaccid and cold, and there was incontinence of urine. A little later tonic rigidity and slow tonic contractions of the arms set in, and the fists were clenched hard. About three hours after the poison had been taken 10 c.cm. of a 10 per cent. solution of sodium thiosulphate was given slowly by intravenous injection; the administration had not been completed before the patient began to rally markedly. At the end of the injection, which had taken some minutes, he began to look around, to smile a little, and to cough, holding his hand over his mouth; uneventful recovery ensued. Schmidt remarks that to see a man who had been unconscious for hours, and who in two or three minutes during an injection suddenly woke to complete consciousness, was most dramatic. The author therefore recommends this treatment as the only effective measure in poisonings of this class; although he admits that it is generally assumed that recovery follows if the patient survives the ingestion of potassium cyanide for an hour, he greatly doubts if his patient would have recovered without the treatment just described.

187. The Intramuscular Injection of Liver Extract.

O. AUBERTIN and VOILLEMIN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, May 19th, 1930, p. 749) report a case of pernicious anaemia in a man who, besides the usual symptoms of asthenia, suffered from marked gastric intolerance so that treatment by liver diet was not possible. On admission to hospital the red cell count was 1,060,000 per c.mm. and the haemoglobin percentage 40; 250 grams of raw calf liver was given daily by the mouth, but the treatment was stopped after five days owing to continuous vomiting and diarrhoea, as the result of which the patient lost nearly 8 lb. in weight. Intramuscular injections of calf liver extract were given, of which 2 c.cm. were estimated to represent 60 grams of raw calf liver; each ampoule

The most efficient Peptonising Powders!

Half a tube of Benger's is enough!

While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1 — Box of 6, 1/-; No. 2 — Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

Prices: 3/-, 5/6 *and* 10/6

BENGER'S FOOD, Ltd., MANCHESTER.

Branch Offices NEW YORK (U.S.A.) 70 Beekman St
SYDNEY (N.S.W.) 350, George St
CAPE TOWN (S.A.). P.O. Box 573

Medical men may obtain full particulars of Benger's preparations post free on request.

Haemoptysis, when no primary disease can be found outside the lungs which might have caused it, very frequently leads to the suspicion of tuberculosis; even the absence of physical signs in the lungs does not negative this. Quite large cavities are sometimes revealed by the x rays, although no definite evidence can be found clinically. We

CASE I.—After lipiodol.

do not propose to discuss the differential diagnosis of haemoptysis, but wish to point out the reality of the difficulty in this condition of dry bronchiectasis; during the last two years we have seen fifteen cases of this disease, and in most of them the presence of tuberculosis has been either diagnosed or suspected.

The general features of bronchiectasis in its ordinary form are well recognized. Textbooks lay particular stress on the typical "bronchiectatic sputum," which separates into three layers in a cylindrical vessel. The sputum is abundant, and often offensive; it is usually evacuated on change of position, especially on rising and going to bed. There are often periodic attacks of fever, and nearly always clubbing; an exception to all these points is found in apical bronchiectasis, in which condition, owing to the position of the lesions, there are no accumulated secretions, often no cough, and usually no clubbing—an indication, when considered with the dry basal type, that clubbing in this disease is certainly due to toxic absorption.

It is possible that the apical type corresponds with the dry basal type to be described, the satisfactory drainage preventing secondary infection. It is also possible that most cases of bronchiectasis, commencing after pneumonia or empyema, start as the dry type and become infected at varying periods; only rarely do necropsies reveal the dry type, for the patient with bronchiectasis dies from toxaemia after the cavities have become infected. The mere fact that there is no clubbing of the fingers is always a point in favour of the diagnosis of tuberculosis as against bronchiectasis, the apical type and the dry basal type being exceptions to this rule. Since the introduction of lipiodol injection as a means of visualizing the bronchial tree, it has been possible to demonstrate the presence of bronchiectasis in cases in which the amount of sputum is negligible, and it has been our custom to carry out this investigation in any doubtful case, the cases recorded below proving the evidence of its value.

The condition of dilatation of the bronchi without secretion was described by Reinberg[1] under the name of dry bronchiectasis; the following case is a typical example.

CASE I.

A girl, aged 20, had had pneumonia when 8 years old; since then she had been troubled by a cough, with occasional slight expectoration and for twelve years she had been under observation at a tuberculosis dispensary.

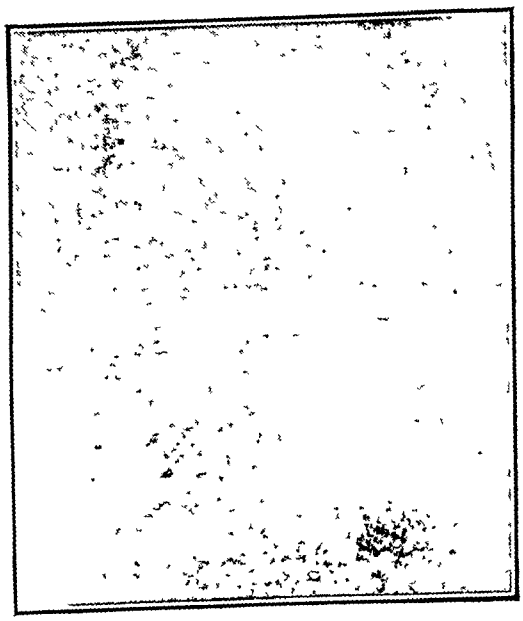
On examination she was found to be a well-developed, healthy-looking girl. No clubbing was present. The physical signs consisted of an impaired note, and diminished breath sounds at the left base behind. The heart was not displaced, but a skiagram showed some increase of shadows in the left basal region. After lipiodol injection well-marked cylindrical and sacculated bronchiectasis was revealed.

The occurrence of haemoptysis in bronchiectasis was pointed out by Goumbault[2] as long ago as 1859, but in these cases the diagnosis was made on the presence of typical physical signs and sputum. After the introduction of intratracheal lipiodol injection it was established that "haemoptysis" might occur in cases of bronchiectasis which gave none of the typical signs or symptoms of the condition.

CASE II.

A woman, aged 28, had had "influenza" eight years before; since then she had been quite well for six years, when she had a haemoptysis. She continued at work during the last two months. She had had repeated haemoptyses, 15 oz. in all.

Her general condition was found to be quite good, and the physical signs in the chest were very indefinite. She was examined by three highly competent clinicians, who were unable to find definite signs which would suggest the origin of the bleeding. No clubbing was present, and the skiagram showed no abnormality. After lipiodol injection an extensive glove-finger type of bronchiectasis was demonstrated.



CASE III.

A girl, aged 14, had had pneumonia two years previously, since when there had been a cough, with occasional expectoration. Six months before the examination took place she had had a haemoptysis (3 oz.).

On admission she was found to be a well-developed healthy-looking child, with no clubbing. At the right base there was an impaired percussion note and diminished breath sounds, but no added sounds. While in hospital the patient produced no sputum. The skiagram showed no abnormality, but lipiodol injection demonstrated a well-marked bronchiectasis.

CASE IV.

A man, aged 51, six years previously had had a left empyema, for which he was treated by open drainage. Since then there had been a slight cough, with occasional sputum. No medical advice was sought until two months before admission, when he had a haemoptysis of 10 oz. When seen as an out-patient he was having another haemoptysis, which amounted to 10 oz.

CASE IV.—After lipiodol. Lateral view.

He was a short, robust man, with emphysema; the scar of an empyema drainage wound was visible at the right base behind. Around this region there was bronchial breathing, with a few added sounds. The skiagram showed no abnormality except the resected rib. After lipiodol injection the antero-posterior view showed no definite bronchiectasis, but a lateral view revealed a well-marked saccular bronchiectasis behind.

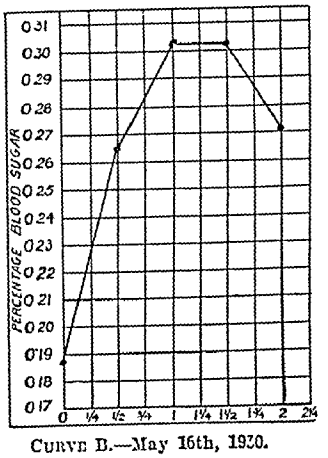
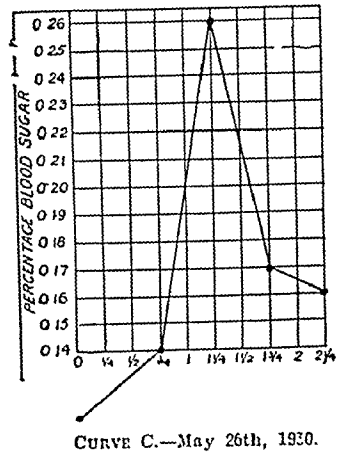
FOUR DIFFERENT TYPES OF BLOOD SUGAR CURVE IN ONE PATIENT WITHIN SEVENTEEN MONTHS.

BY

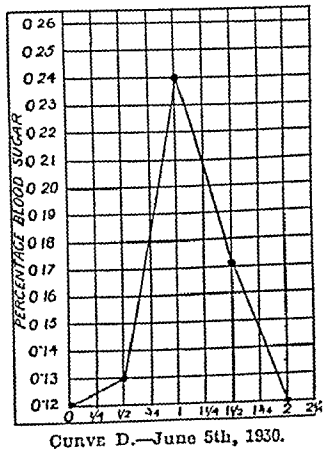


F. J. G. LISHMAN, M.B., B.S.,
UNIVERSITY COLLEGE HOSPITAL.

THE following details appear to be of some pathological interest, and may also be of importance in connexion with life insurance of glycosuric subjects.



An obese butcher, aged 50, came under treatment in January, 1929, for osteo-arthritis of the knee- and ankle-joints; owing to the discovery of glycosuria on routine examination, a blood sugar examination was made (A). The curve was found to be normal, but indicated a low renal threshold of 0.128 per cent. sugar.



CURVE A.—January 28th, 1929.

CURVE B.—May 16th, 1930.

CURVE C.—May 26th, 1930.

CURVE D.—June 5th, 1930.

CURVE A.—Fasting blood sugar (not estimated). Glucose 40 grams by mouth. Blood sugar: 1/2 hour after, 0.108 per cent.; 1 hour after, 0.128 per cent., 1½ hours after, 0.095 per cent.; 2 hours after, 0.077 per cent. Urine: fasting, 0; 1/2 hour after glucose, 0; 1 hour after glucose, ++, 1½ hours after glucose, +; 2 hours after glucose, +.

CURVE B.—Fasting blood sugar, 0.188 per cent. Glucose, 40 grams by mouth. Blood sugar: 1/2 hour after, 0.266 per cent; 1 hour after, 0.304 per cent., 1½ hours after, 0.304 per cent.; 2 hours after, 0.272 per cent. Urine: fasting, +; 1/2 hour after glucose, ++; 1 hour after glucose, ++; 1½ hours after glucose, ++; 2 hours after glucose, ++.

CURVE C.—Fasting blood sugar, 0.095 per cent. Glucose, 50 grams by mouth. Blood sugar: 3/4 hour after, 0.14 per cent; 1½ hours after, 0.26 per cent., 1¾ hours after, 0.17 per cent.; 2½ hours after, 0.16 per cent. Urine: fasting, sugar 0, acetone +; 3/4 hour after, sugar 0, acetone +, 1¼ hours after, sugar +, acetone trace; 2¼ hours after, sugar trace, acetone 0.

CURVE D.—Fasting blood sugar, 0.124 per cent. Glucose, 50 grams by mouth. Blood sugar: 1/2 hour after, 0.132 per cent.; 1 hour after, 0.24 per cent., 1¼ hours after, 0.172 per cent.; 2 hours after, 0.12 per cent. Urine sugar: fasting, 0; 1/2 hour after, 0; 1 hour after, 0, 1½ hours after, +, 2 hours after, +.

(The figures at the base of the charts represent the time in hours after administration of glucose.)

The patient's teeth were extracted, and he was treated by radiant heat baths, and also by thyroid gland (dried) 1 gram daily till April, 1930. During eleven months of this period he lost weight slowly, presumably owing to the action of the thyroid; but he rapidly lost 5 st. in the course of four months, concurrently with the development of symptoms of thirst and polyuria, and the presence of increased quantities of sugar, together with ketone bodies and albumin in the urine. This was so suggestive of diabetes mellitus that a second curve (B) was prepared after re-admission to hospital, the patient having been kept on a light diet, with restricted carbohydrate only, and without thyroid, for four days. This curve was typical of diabetes mellitus, but sugar was passed in the urine throughout.

The patient was put on a strict diabetic diet of approximately 1,000 calories containing 25 grams of carbohydrate, 58 grams of protein, and 75 grams of fat; the symptoms of thirst and polyuria then disappeared, and he became completely free from sugar in two days. Owing to the cessation of the glycosuria, suggesting that the renal threshold might now be higher, a third curve (C) was prepared to determine the threshold. This, while still being of the diabetic type, and not returning to normal within two hours, was suggestive of the "lag" type of curve; sugar was not passed until one and a half hours after the administration of the glucose, the blood sugar then being 0.21 per cent. The diet was increased to 1,500 calories (carbohydrate, 43 grams; protein, 78 grams; fat, 112 grams); the patient remained without symptoms, and the urine continued to be sugar-free, with only traces of albumin and ketone bodies. After another ten days' interval a final curve was made; this was definitely of the "lag" type. The patient had had no thyroid for twenty-seven days previously, was never given insulin, and was not of Jewish extraction. He had no complications of diabetes mellitus.

I am indebted to Dr. Batty Shaw for permission to publish this case, and to Dr. G. W. Goodhart and Dr. B. W. S. Mackenzie for the blood sugar estimations.

SUBSEQUENT HISTORY OF PATIENTS TREATED WITH A RESIDUAL ANTIGEN OF B. TUBERCULOSIS.

BY

C. E. JENKINS, M.R.C.S., L.R.C.P.,
PATHOLOGIST TO SALFORD ROYAL HOSPITAL.

IT is probable that in no disease is the value of a remedy more dependent upon remote results than in pulmonary tuberculosis. A preliminary paper in which I described the preparation of the antigen and the immediate results obtained was published in 1928 in the July issue of the *British Journal of Tuberculosis*, and the present note deals with the after-history of the cases then described. At that time no patient was refused treatment because of the state of the disease; consequently, the records were not improved by the fate of these hopeless cases. It was desired to test the antigen thoroughly, and the only requirement was that there should be no doubt about the certainty of the diagnosis. The sputum was positive in 79 per cent.; the remaining patients had had positive sputa in the past, or had spent one or more periods in sanatoriums, and presented clinical signs and symptoms that were unquestionable.

Of 67 consecutive cases reported, 10 patients died during or shortly after the treatment, 12 were not improved and were classified as failures, and 45 were said to show definite clinical improvement after a course of treatment lasting three months. The assessment was made immediately the course finished, in every case by the clinician in charge of the patient, usually the private doctor. Care was taken that the present writer offered no opinion on a case. All these cases have now been traced after an interval of two to three years has elapsed, and the results are here set forth.

The original deaths and the original failures are added together, since such deaths are obviously part of the original failures; they form a group of patients numbering 22, of whom 2 had improved, 4 had not improved, 15 had died, and one was untraced. Thus the percentage of those improved was 9, and of those now alive 29.

The patients who were originally improved numbered 45; of these, 32 were found to be still improved after two or three years, 6 had not improved, 5 had died, and 2 could not be traced. The percentage of those improved was 74, and of those now alive 88.

These results support the original observation that the conditions requisite for success with antigenic treatment in pulmonary tuberculosis are the same as for antigenic treatment of any other disease. It is essential for success that the patient shall possess some reserve of resistance, although that factor may need the antigen to call it into operation.

Reviews.

THE PHYSIOLOGY OF SENSATION.

The sensory phenomena attending the division and subsequent regeneration of peripheral nerves have attracted considerable attention since the classical work of Head, and the conceptions which arose out of that work have been the subject of a good deal of further work and of much controversy. The occasional accidents of daily life, and the innumerable injuries suffered in the war, have given Professor J. S. B. Stopford an opportunity to study the question anew, and the results of his investigations are given in his recent book on *Sensation and the Sensory Pathway*.[1] The results reached by him are so satisfying that it can be said without hesitation that by a rare combination of observation, deduction, and philosophic synthesis he has made a most valuable contribution to the subject.

Stopford has not only closely confirmed most of Head's observations, but has made further progress in the same direction. Cutaneous sensibility he regards, much as Head did, as falling into two categories: the finer, discriminative sensibility, of more recent phylogenetic acquisition, with the interpretation of which the sensory cortex is mainly concerned; and the quite distinct, cruder, protective sensations, affective in quality and exhibiting an all-or-none character of response, which are dealt with mainly by the thalamus. Careful analysis of deep sensibility shows that this also is divisible into sensations of two types—primitive protective and finer discriminative, the latter being concerned particularly with localization and with the appreciation of passive movement. The loss and dissociation of sensation following the division and suture of a peripheral nerve may, under suitable conditions, extend to the deep sensibility, which may also show an earlier return of the more primitive components of sensation. It is, moreover, noteworthy that in the glans penis the deep sensibility shows a lack of localization and a strongly affective character—qualities which are comparable with those of the purely "protopathic" superficial sensibility of the same region, and with similar qualities of both deep and superficial sensibility in skin areas during the first stage of recovery from nerve section.

In Head's experiments on his own hand, the nerves divided—radial and musculo-cutaneous—were apparently almost purely cutaneous, but this is by no means the case in all subjects. Stopford has found, by detailed anatomical and clinical studies, that the subcutaneous supply to the hands and digits comprises fibres for tactile pressure and pressure pain which mainly accompany tendons and blood vessels, and to a lesser extent fibres from main deep or cutaneous nerves and those responsible for the finer elements of deep sensibility, such as posture recognition and localization, which are supplied by branches from the ulnar, median, and cutaneous nerves. The fundamentally different types of sensation have separate paths in the spinal cord—the primitive protective type crossing over to ascend in the posterior spino-thalamic tract of the opposite side, while the finer discriminative functions are related to the phylogenetically more recent posterior columns of the same side. In the brain stem there is further separation of these discrimination tracts into those concerned with tactile discrimination and those for position sense. The axones of the tertiary neurones represent two main streams—one to the affective nucleus of the thalamus, and one to the sensory cortex. The thalamus is concerned with the crude protective functions and the affective aspects of sensation; its response is of the all-or-none character, so that when it is released from the inhibitory control of the sensory cortex there is affective overaction in sensation. The sensory cortex is essential for localizations and discriminations; it responds to different strengths of stimuli, and enables comparisons to be made between them.

After nerve section and primary suture, the recovery of both superficial and deep sensibility occurs in two closely comparable stages, the return of discrimination in both instances being delayed and rarely complete; after secondary suture the return of the discriminative properties of the sensations is much less complete, and not infrequently altogether lacking. For clinical purposes it is convenient to disregard the subdivision into superficial and deep, and to separate sensation into two kinds, one served by the thalamic system, the other by the cortical. The former is protective and affective in type, the latter discriminative; each, as already explained, includes both superficial and deep components; the thalamic returns first and most completely, the cortical later and less completely. The reason why recovery is delayed and incomplete in the latter is simple and adequate; it is due to the crossing of fibres on regeneration, and to the fact that the sensations depend, not on the end-organ, but on the central connexions. The thalamic connexions, being relatively simple, will be established early; whereas the cortical connexions will need much re-education. Until this process has advanced far enough to give proper function the cortical inhibition of the thalamus will not make itself evident, with the result that there will be affective overaction. Professor Stopford presents his thesis with great skill and clarity, and he has succeeded in throwing much light upon this interesting and important subject.

[1] *Sensation and the Sensory Pathway.* By John S. B. Stopford, M.D., F.R.S. London: Longmans, Green and Co. 1930. (5½ × 9, pp. xii + 148; 17 figures. 7s. 6d. net.)

JOINT INJURIES.

The fact that Sir Robert Jones's little book on *Injuries to Joints*,[2] has reached a third edition, and that eleven impressions of it have been necessary in fifteen years to meet the demand, shows that it does far more than merely meet the needs of practitioners who, as the preface to the first edition expressed it, had "left the quiet paths of private practice for the more eventful career of military surgery." The first edition was reviewed in our issue of September 25th, 1918. The author in this, the third edition, has, he tells us, been careful not to change the character of the book in any way, but he has enlisted the services of Mr. Harry Platt of Manchester, and together they have brought it up to date and rewritten some parts, such as those on ischaemic paralysis in relation to its causation and prevention. Although this disease can hardly be claimed as the result of an injury to a joint or joints, yet as it may and does occur during the treatment of injuries of joints, and can be such a tragedy for the patient, and even more so for the surgeon's reputation and pocket, we are glad that Sir Robert Jones and Mr. Platt have disregarded the bonds of strict definition and have included it.

We have here, from the pen of a master, in less than two hundred diminutive pages, a vast amount of good advice and sound teaching in the bloodless surgery of joints. The reader of this book who pays heed to these precepts may be sure that in following them he is taking the best course for his patients and for himself. Expert advice as to what position or what splint he should choose for putting up any injury to a particular joint is placed at his disposal, and the advice is given in clear, plain language.

We are a little doubtful as to the author's meaning in his remarks on the operative treatment of hallux valgus. We fully agree with him that a pseudarthrosis should be aimed at by excision of the metatarsal head, and the freer the resulting movement the better, but what does he mean by excision of the joint, which he deprecates? We must confess that we do not know who are the surgeons who recommend removal of the base of the phalanx as well as the head of the metatarsal for this deformity. We are interested to find that Sir Robert Jones still advocates excision of portions of the tendons of the long and short peronei for certain forms of spasmodic flat-foot. In the discussion on this subject at the Royal Society of Medicine, on which we commented on March 15th last, most of the speakers had either abandoned this treatment or resorted to it only rarely. That it is efficacious we can testify from experience.

[2] *Injuries to Joints.* By Sir Robert Jones, Bt., K.B.E., C.B., Ch.M., F.R.C.S., F.A.C.S. Third edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1930. (Fcap. 8vo, pp. 195; 183 figures. 6s. net.)

to be most convincing. Chapters on marasmus and on vomiting in infancy are particularly valuable for the wealth of practical detail they contain, but unfortunately the chapter on diarrhœa is rather spoilt by too great an insistence on the importance of otitis media as a factor in severe cases. There is also a surprising passage on page 103, which seems to mean that while a very young baby can go through the night without being fed, it "may be advisable to resume one of the night nursings" later on in the first year. One other criticism is that in describing congenital pyloric stenosis Dr. Marriott does not consider the feeling of the tumour essential in diagnosis. This statement is surely out of date as far as English workers are concerned, and can only lead to confusion between real stenosis cases and examples of pylorospasm. Chapters on rickets, tetany, and scurvy are included, and there is an wholly admirable exposition on anhydraemia, acidosis, and alkalosis, written in conjunction with A. F. Hartmann. Throughout the book details of cases are given, and it is obvious that the work is based upon wide clinical experience. It can be warmly recommended to all students of the difficult art of infant feeding.

DR. BERNARD MYERS has contributed a little book on *Modern Infant-Feeding*[7] to the "Modern Treatment Series," and it must be admitted that this modest volume comes well out of an inevitable comparison with Marriott's larger textbook. Dr. Myers also bases his advice upon physiological principles, and his chapter on breast-feeding is particularly good. In his summary of the best methods of artificial feeding the comments on lactic acid milk are especially good, but the details about the size of feeds are too condensed, so that the account of caloric feeding will almost certainly be unintelligible to anyone without a sound previous acquaintance with this subject. This handy pocket-book is well produced, but contains an unnecessary number of italicized passages, which spoil the appearance of many pages.

NOTES ON BOOKS.

MISS LYLA M. OLSON, in her *Improvised Equipment in the Home Care of the Sick*,[8] expresses her thoroughness by inditing separate prefaces, or invocations, on separate pages, to the private duty nurse, the public health nurse, and the student nurse. A further preface to the general public tells how Miss Olson had difficulty in collecting improvised equipment for the purpose of a demonstration sponsored by the Minnesota Board of Examiners of Nurses. The book is well illustrated, and shows a number of ingenious devices made out of grocery boxes, wooden barrels, chairs, bricks, and other odds and ends. Miss NORMA SELBERT'S little book on the *Home Care of the Sick*[9] is described as a non-technical book, written for the benefit of "homemakers" and for "students who are carrying vocational courses in high schools and colleges." If the homemaker is sufficiently level-headed not to be frightened by the numerous duties imposed upon her, she will no doubt learn much from Miss Selbert.

The English edition of Messrs. MERCK'S *Annual Report*[10] now appears in three parts a year. Part III for 1929 contains two short articles on tropical diseases, which are of general interest. Dr. Heraldo Maciel reports on the treatment of hookworm infection among sailors by carbon tetrachloride. A single dose of 4 grams cured 70 per cent. of cases, and no toxic effects were observed. Dr. D. Teitel writes on the treatment of amœbic dysentery in infants. The article is an abstract of an address delivered at the first Paediatric Conference at Jerusalem. The results produced by emetine, yatren, and stovarsol are compared. Emetine was the most effective and yatren the least effective, whilst stovarsol produced the highest incidence of toxic effects. The author concluded that emetine was the most important of these remedies. The best results were obtained by commencing treatment with emetine and continuing with one of the other drugs. These conclusions were drawn from the results of about six hundred cases. The report also contains short notices of a number of drugs. Plasmochin, the new quinine substitute, is stated to have the composition of alkylamino-6-methoxy quinoline. It is best given in small doses (0.02 gram) repeated three to five times a day. This method avoids the unpleasant toxic effects that may be produced by large doses. A number of reports regarding the use of thallium acetate as a depilatory have been brought together, and it is concluded that the dose should not be repeated even after an interval of some months, and that it is unsafe to use thallium after puberty. Part I for 1930 contains an interesting article by Professor Carrasco on the history of the ancient University of Salamanca. This was founded early in the thirteenth century, and in the fourteenth century ranked with Paris, Bologna, and Oxford as one of the four famous universities of the world. Unfortunately it remained unaffected by the intellectual movement of the Renaissance, and in consequence declined during the seventeenth and eighteenth centuries. During the present century there has been a fresh development of activity, especially in its medical school, and the future of this ancient seat of learning appears hopeful.

Aids to Zoology,[11] by H. LISTER, is a brief outline of systematic zoology suitable for students who are revising the subject for preliminary examinations. The text is clearly arranged, and is illustrated by figures and diagrams.

Frequent reference has already been made in these columns to Professor Honigmann's series of textbooks on differential diagnosis, the most recent being to Part IV of volume i of the series which dealt with diseases of the alimentary system (June 21st, 1930). Volume iii of the series is devoted to Practical Differential Diagnosis in Psychiatry.[12] The author is Dr. HERMANN HAYMANN of Badenweiler; and there is an additional section on the diagnostic significance of intelligence tests by Dr. ERICH STERN of Giessen. Under the heading of general symptomatology there is a detailed description of the various bodily and mental symptoms encountered in the psychoses, and the various psychoses themselves are considered seriatim in the ensuing section. The concluding portion of this section deals with the psychoneuroses, latent psychopathic tendencies, and disorders of personality make-up. There is also a chapter on feigned insanity. Each author has contrived to give a compact and reliable account of his subject, and the work is one which will commend itself to all psychiatrists and specialists in mental defect.

PREPARATIONS AND APPLIANCES.

A MASTOID WOUND RETRACTOR.

MR. W. M. MOLLISON, M.Ch., F.R.C.S., writes: The illustration shows a simple self-retaining mastoid wound retractor which has proved itself most satisfactory in use. It is lightly but strongly made, and is so curved that when the jaws are in position the shafts and handle lie conveniently against the

head of the patient out of the way. It is fitted with a cam ratchet, which maintains the jaws at any desired width with delicacy and rigidity.

The instrument, which can be taken apart at the joint, is made of stainless steel so as to withstand repeated sterilizations without damage. It was made to my design by Messrs. Down Bros., Ltd., 21 and 23, St. Thomas's Street.

vaccinated population, the vaccinated have not been exposed to infection. This is a fallacy, for here, as elsewhere, we have a large population which was vaccinated during the war. Not one of these men has contracted small-pox, though many, including not a few whose wives contracted the disease, were as freely exposed to infection as were doctors and nurses. Forty extensions of the present outbreak of small-pox consisted of a single case in a fresh neighbourhood. In seventeen of these cases every house contact (three on an average) was traced and vaccinated; thanks to these precautions, each outbreak was limited to the one initial case. No case has occurred in any contact vaccinated within seventy-two hours of exposure to infection—that is, to an eruption; late vaccinations, while sometimes effective, were unreliable, although the cases were usually modified to such an extent that they would frequently have been missed had it not been for careful medical inspection for twenty-one days after exposure to infection.

The classification of 570 cases of small-pox admitted to the Snarestone Small-pox Hospital was as follows: unvaccinated, 450; vaccinated in infancy, 63; and vaccinated late as contacts, 57. Of those vaccinated in infancy the highest age was 75 years, the lowest 38 years, the average age being 51 years.

Statistics Relating to Severity.

The following classification refers to the eruption in 560 cases:

Mild cases	243 (43.5 per cent.)
Discrete cases	243 (43.5 per cent.)
Very mild cases	68 (12 per cent.)
Confluent cases	6 (1 per cent.)

The eruption of 53 patients vaccinated as contacts, and later developing minor small-pox, was classified as follows:

Mild cases	22 (42 per cent.)
Very mild cases	16 (30 per cent.)
Discrete cases	15 (28 per cent.)

From these figures it will be observed that of the total admissions to hospital 12 per cent. had a very mild attack, compared with 30 per cent. in those vaccinated late as contacts.

Although vaccination, more than two or at the most three days after the first exposure to infection, could not be relied upon as protection for any single individual, it has been our practice to advise it in all infected households, for in the event of one or more of a family developing the disease the remainder would then enjoy absolute immunity, and the house would be given its clearance.

I take this opportunity to express my indebtedness to Dr. J. A. Fairer, medical officer of health for Leicestershire, for his permission to publish these notes, and also to Dr. J. E. O'Connor for his invaluable assistance in many difficult diagnoses.

Frank T. Doleman, M.R.C.S., L.R.C.P.,
Assistant Medical Officer for Small-pox, Leicestershire.

MEDICAL EDUCATION IN INDIA.

[From a Correspondent.]

The reference in the *British Medical Journal* of July 5th (p. 38) to the conference called by the Government of India on June 23rd and 24th to consider the maintenance of adequate standards in provincial institutions for medical education is of great interest. The *Times* correspondent states that there was a unanimous agreement between the representatives of the provincial Governments and representatives of the Indian universities on the desirability of establishing an All-India Medical Council to ensure proper standards and qualifications. The next step is for the Government of India to enact legislation. A bill is to be prepared forthwith, and the local Governments are to be consulted on the details in time for submission to the Central Legislature at the Delhi session early in 1931. The indications are that we may look forward to the organization of a central council. Such a council has long been needed in India, wherein medical education on an All-India basis may be discussed, and the differing standards of qualifications, in the separate and widely separated provincial institutions, may be studied and a system of registration adopted to meet the requirements of All-India.

The history of former medical bills prepared by private members of the Legislature and submitted to provincial Governments for opinion has shown how many diverse problems appear and call for solution; and all the bills hitherto considered have had to be dropped. There will, of course, be difficulties in the present attempt, and perhaps delays. The Medical Acts in force in this country were for many years under discussion before they reached the Statute Book. And in India, though much ground has been covered by previous discussions, new problems are appearing with the approach of responsible government and the political developments under the new constitution. It is an all-important step in advance now to be undertaken, and all who are concerned with medical education, and appreciate the incalculable benefits that may accrue to the public health of India, will wish the new movement every success, and watch its progress with sympathy and understanding. A review of the present position of medical education in India will probably prove essential as a preliminary step. Perhaps this has already been undertaken. A detailed record is required as a basis of legislation, and will be of great assistance to the lay members of the Legislature when the bill comes under discussion.

There is no mention in the telegrams from India as to whether the object, or one of the objects, of the proposed council will be to arrange that the qualifications granted in India may, by agreement with the General Medical Council in Great Britain, become registrable in this country. It seems probable that this may be one of the objects, for a further resolution of the conference expressed regret at the decision of the General Medical Council to withdraw the conditional recognition of medical degrees granted by the Universities of Bombay, Calcutta, Lucknow, and the Punjab. This decision gave rise at the time to expressions of indignation in India, and to severe and violent denunciations in the press. But as similar views have been voiced during the last three or four years, and more especially in the Legislative Assembly in 1929, when the conditions under which these degrees could remain registrable in Great Britain were debated, it is possible that the extreme views were influenced by political and racial feeling, as well as by lack of acquaintance with the facts. The views may be moderated as information spreads and political feeling becomes less acute.

Thoughtful members of the medical profession are gradually freeing from political entanglements the question of improving medical education, as can be surmised from the reasonable expression of regret in the wording of the resolution referred to. This resolution mentions only four* of the eight Indian universities granting medical degrees, as the degrees granted at Patna, Andhra, and Rangoon Universities have never been registrable in Great Britain. They are all registrable in India, as are certain diplomas granted by local licensing bodies. The "licensed medical practitioners"—a numerous class—are also registrable in India, though the courses of instruction and the examinations are not recognized for degrees given by any of the Indian universities.

The problems concerning recognition and registration of qualifications which represent widely different standards of education will call for much patient study and careful consideration by the Indian council now about to be constituted. It would seem that sooner or later this body will find itself the authority for the maintenance of an All-India register of persons holding qualifications granted in India or practising in India. The procedure, requirements, and terms for admission to the Indian register of recognized qualifications granted outside India will fall to be devised in due course. Certain requirements will then be laid down for registration in India, just as certain requirements are laid down for registration in Great Britain. And when this is done there should be no lack of opportunity for the Indian authorities, should they so desire, to raise the question of recognition of Indian degrees with the Council in Great Britain.

The lapse in the recognition of some of the Indian degrees in Great Britain was due to the non-fulfilment by India of the present requirements deemed necessary for admission to the British *Register*. On this question many correspondents to the press in India have laboured under a complete misapprehension, and have in effect claimed the right of unconditional admission of Indian graduates to the British *Medical Register*. The requirements for admission to the British *Register* rest with the authorities in Great Britain, and in the same way the requirements for admission to the Indian register will, when a responsible and authoritative council is constituted in India, rest with the authorities in India.

*Madras is not referred to in the telegram.

will be found to have advanced medical science, and to have helped to a clearer conception and more adequate solution of the hygienic and social problems to which the contribution of medicine should be paramount. The presidential address of Professor Harvey Smith will not be least among its valuable features. We should like to accord to our Canadian brethren, and to the affiliated Canadian Medical Association, our thanks for their most hospitable welcome.

OUR CANADIAN SUPPLEMENT.

Throughout this week the British Medical Association has been holding its ninety-eighth Annual Meeting at Winnipeg in conjunction with the sixty-first Annual Meeting of the Canadian Medical Association. In order to commemorate this event we publish with our present issue a special *Canadian Supplement*. Its contents include Professor Harvey Smith's presidential address to the Association on Medicine in Canada, to which reference is made above; the full text of Lord Moynihan's eloquent Listerian Oration; and three of the clinical addresses which the local executive invited leaders of the profession from these islands to deliver at special afternoon sessions in the Winter Club at Winnipeg. The subject of Sir Lenthal Cheatle's address is the primary tumour in carcinoma of the breast; Sir William de Courcy Wheeler discusses the significance of surgical recoil following visceral decompression; and Professor W. E. Dixon returns to the problem of drug addiction, to which he has devoted much attention for years past. Exigencies of space and time prevent us from giving any detailed account this week of the proceedings at Winnipeg, other than the note on page 329, but brief cabled messages have already assured us of the success of the Annual Meeting on its social and scientific sides. We hope that the *Canadian Supplement* will be read for its intrinsic interest by members of the Association at large, and that those who have taken part in the Winnipeg Meeting of 1930 will value it as a memento.

CONVENTION NUMBER OF THE "CANADIAN MEDICAL ASSOCIATION JOURNAL"

The August issue of the *Canadian Medical Association Journal* is issued in the form of a special number devoted to the Meeting at Winnipeg of the British and Canadian Medical Associations. A frontispiece reproduces photographs of the three presidents concerned—namely, Professor A. H. Burgess, president of the British Medical Association; Dr. A. T. Bazin of Montreal, president of the Canadian Medical Association; and Professor W. Harvey Smith, president-elect of the two Associations. This number of the Canadian Journal opens with a "word of welcome" to visitors from overseas and the United States of America. It is recalled that the first Meeting of the British Medical Association in Canada was held in 1897 in Montreal, "the commercial metropolis . . . the tolerant home of two diverse yet complementary national civilizations." The second Meeting took place in 1906 in Toronto, "the Queen City, the friend of literature, art, and music . . . the stronghold of the more purely British tradition." The third Meeting, now in progress, is experiencing the hospitality of Winnipeg, "the exponent of the enterprise, resourcefulness, and optimism of the breezy West." This word of welcome contains a significant sentence: "Canada is grown-up now, and is conscious of a new life and a broader outlook," a sentiment which represents also the state of affairs as regards the profession of medicine in the British Empire and the position of the British Medical Association. Reference is made to the honourable place taken in the advance of science by leaders of Canadian medicine, as well as by the rank and file. Among the editorial notes is a reference to the *Book of Canada*, a volume of some 250 pages, worthily presenting life and work in that Dominion, and reflecting great credit on Professor Chester Martin and the committee associated with him. An editorial article, signed by Dr. A. Grant Fleming, on the proposals of the British Medical Association for a general medical service for the nation, is followed by a paper by Dr. W. H. Hattie, in which the probable future of medicine is contemplated as "a principal factor in making man's life really worth while." Among the numerous clinical contributions special topical interest attaches to a discussion by Dr. M. R. Bow, Deputy Minister of Health for Alberta, of maternal mortality as a public health problem. Dr. A. T. Bazin discusses elsewhere in the issue the surgical problems presented by the diabetic patient, and other topics dealt with include: insulin; pitfalls in the clinical application and interpretation of the basal metabolic rate; the surgical treatment of tuberculous empyema; the living suture operation in ventral and inguinal hernia; health insurance in British Columbia; diphtheria toxoid; the mechanism of cancer development; and the radical treatment of traumatic epilepsy. In conclusion may be quoted some of the final sentences of the preliminary word of welcome. "Not the least of the benefits to be derived from a meeting such as this in Winnipeg is that our problems will be discussed formally and informally, on the platform, on the links, and amound the festive board, from different angles. . . . Much may be expected from this interchange of ideas. Englishmen, Scotsmen, Welshmen, Irishmen, Australians, New Zealanders, Canadians, are meeting shortly in the centre of Canada. The sense of brotherhood which already binds us together as members of one great Empire will inevitably be strengthened by the association, by the struggle towards our common goal, and the realization of our common successes. Again, a welcome to all."

BRITISH ASSOCIATION IN BRISTOL.

The British Association for the Advancement of Science meets this year in Bristol from September 3rd to 10th, under the presidency of Professor F. O. Bower. Information about the Sections has been given already in the *British Medical Journal* (May 17th, p. 917). The two Sections of most direct interest to the medical profession are those of physiology and psychology. In the first of these Professor H. S. Raper has chosen for the subject of his presidential address "Synthetic activities of the cell"; this will be delivered on Thursday, September 4th, and will be followed by a discussion. Other subjects which will be dealt with in this Section are: pseudo-isochromatism and the detection of colour-blindness; the blood groups and their inheritance; the removal of lactic acid after exercise in the mammal; quantitative aspects of the action of drugs; the factor concerned in diabetic coma; the function of carbon dioxide; and some unpublished work on the heart. A joint meeting of the two Sections will be held on Monday, September 8th, to discuss the question: In what sense can we speak of primary colours? Professor C. W. Valentine, president of the Section of Psychology, will deliver his address on Friday, September 5th, taking for his subject "The foundations of child psychology." For the previous day a discussion has been arranged on certain psychological problems of adolescence, including the following topics: variations in the emotional development of normal adolescents; adaptation in youth as illustrated by the difficulties of the mental defective; adolescent modes of thinking; and the adolescence of the young wage-earner. Other points of psychological interest which will receive

205. Lung Complications following Operations.

E. N. Stahnke (*Zentralbl. f. Chir.*, May 31st, 1930, p. 1333) classifies post-operative chest conditions as: (1) purulent bronchitis, broncho-pneumonia, and pneumonia; (2) complications caused by aspiration (often with similar signs to the above, but distinguished by their course; and (3) embolic conditions (not dealt with in his article). The type of anaesthesia has little effect on the number of complications, but anaesthesia by inhalation is contraindicated where bronchitis or tuberculosis already exist. Avertin has so far given good results. Chloroform is more often followed by pneumonia than is ether. Infection plays an important part in causation, as does also chilling of the back and extremities during operation. The particularly large number of complications after abdominal section, whether under general or local anaesthesia, is probably explained by the dorsal decubitus of the patient, which places the respiratory muscles at a disadvantage, and by abdominal pain, which hinders full respiratory movement and coughing. The poor abdominal and diaphragmatic movements have an adverse effect on the circulation, and a condition of congestion and relative stagnation arises in the respiratory tract, favouring the development of bacteria. Complications most frequently occur after operations on the upper abdomen (stomach and gall-bladder), but the average age of the patients in this group is considerably more than that in the case of operations on the lower abdomen, such as for appendicitis and hernia. The author recommends protection from infection (neighbouring patients and attendants to be free from respiratory catarrh); treatment of any existing cardio-respiratory condition; and, possibly, the injection of antipneumococcal serum. After operation the patient's respiratory exchange should be improved by preventing apathy, rubbing several times daily with cold damp towels, deep breathing exercises, and inhalations of CO_2 every few hours. The patient should lie on his side, frequently changing from the right to the left. Treatment comprises the same measures associated with the use of expectorants such as camphor, and the author claims to have had some success with optochin, combined with intramuscular injections of the patient's blood.

206. Statistics of Appendicitis.

C. Bruusgaard (*Norsk Mag. f. Laegevid.*, June, 1930, p. 584) states that between October 29th, 1895, and January 1st, 1930, 3,349 cases of acute appendicitis and 3,023 of chronic appendicitis were admitted to the Dranem municipal hospital. Of the acute cases, 1,860 were in male and 1,499 in female patients; 3,053 were operated on in the early stage, and 148 in the interval between the attacks, while 148 received medical treatment only, two patients dying. None of the acutely ill patients was under the age of 2 years, and the oldest was 83. The highest mortality occurred in patients above the age of 40. Peritonitis was absent in 1,771 cases, of which 6 were fatal; 575, of which 32 were fatal, had an encapsuled abscess; 550, of which 14 were fatal, had a local peritonitis; and 232, of which 63 were fatal, had a diffuse peritonitis. The total mortality among the 3,349 patients during the period of thirty-five years was 3.55 per cent. (3.8 among the males and 3.2 among the females). Of the 3,023 chronic cases, 889 were in male and 2,134 in female patients. Most of these patients (1,203 cases) were between the ages of 20 and 30; 8 died, of whom 5 were males and 3 females—a mortality of 2 1 per cent.—the causes of death being pulmonary embolism in 4, peritonitis in 2, heart failure in 1, and unknown in 1.

207. Treatment of Recurring Dislocation of the Shoulder.

Mauclaire (*Bull. et Mem. Soc. Nat. de Chir.*, July 5th, 1930, p. 878) summarizes the chief causes of recurring dislocation of the shoulder as follows: dilatation of the capsule, which may be total or partial, anterior or inferior; a tear in the capsule made at the first dislocation; a posterior notch in the humeral head; alteration, flattening and posterior disorientation of the glenoid cavity; and tearing away of the long portion of the biceps and of the supra- and sub-spinous and sub-capsular muscles. To remedy these various lesions the insertion of osseous abutments has been attempted, the first case being that of Eden in 1920, who inserted bone grafts from the tibia in front of the glenoid cavity. A personal case is here recorded, in which good results were obtained by this method and have been maintained for six years. The capsule was first opened and folded cross-wise; tibial grafts were then inserted in front of and below the lower part of the glenoid cavity (the point where the humeral head had escaped). Subsequent radiographs showed that the anterior grafts had coalesced, while the lower ones could still be seen. Mauclaire mentions that these abutments should be examined at long intervals, since some authorities have noted that some undergo a late resorption. Mauclaire, however, believes that they are often replaced by fibrous ones, and that osteo-periosteal grafting, either alone or in combination with lengthening of the coracoid process, is the best technique to follow. Before operating, radiographs should be taken of the humeral head and glenoid cavity; at the operation the joint and capsule should be explored. The latter, often distended, should be very tightly folded, and if a diverticulum is present this should be eradicated by folding. Shortening of the often elongated subscapular muscle is important. In serious cases, as epileptics, it is necessary to perform a sort of reconstitutive arthroplasty by combining the grafts, the coracoid abutment, suture of the tear, the capsular folding, its closure in front and below, and tendino-muscular resection and shortening.

Therapeutics.

208. Ephedrine in Myasthenia Gravis.

Harriet Edgeworth (*Journ. Amer. Med. Assoc.*, April 12th, 1930, p. 1136) describes a personal experience of influenzal pneumonia in which, after a relapse, severe prostration and tachycardia developed without evidence of organic disease. Several months were spent in bed and she then resumed work, but the pulse rate was still 100–120, and the lassitude persisted for five years, when, in 1924, slight ptosis and intermittent diplopia appeared. Six months later, during a pharyngeal infection, the intermittent diplopia became still more severe, and there was great prostration; on several occasions there was weakness of the right arm. Ptosis and diplopia increased, with weakness of the left ocular muscles and in the legs. She could not open the left eye, move the left side of the face, or swallow without nasal regurgitation. A diagnosis of myasthenia gravis was made. By 1927 she was quite helpless; mastication, swallowing, and breathing were difficult, there was severe cyanosis, and an electrocardiogram showed myocardial weakness. In 1928 a chronic sinus infection was relieved and the myasthenic symptoms were improved by the administration of an autogenous vaccine. Thyroid extract and adrenaline generally had adverse effects. In 1929 she commenced taking ephedrine tablets (1/8 grain) and amidopyrin (1½ grains) for dysmenorrhoea; this was followed by gain in muscular strength, but when the ephedrine was discontinued weakness returned. She states that she is now taking (ephedrine 3/4 grain) almost daily, and there is distinct though slow improvement.

209. Iodine in Cutaneous Tuberculous Infections.

J. J. Jensen (*Ugeskrift for Laeger*, June 5th, 1930, p. 550) recounts his experiences as a veterinary surgeon with tuberculous infections of the fingers contracted in the handling of tuberculous carcasses. On one occasion, while handling a heavily infected carcass, he made a deep incision into one of his fingers beside the nail. The wound, which was treated with tincture of iodine, healed quickly, but about a month later a slightly tender swelling developed at the same spot; a tiny fistula formed, and a little purulent fluid escaped. The fistula closed periodically, only to open again, and this state of affairs went on for months, in spite of repeated paintings with tincture of iodine. The treatment was now changed to painting with a strong mixture of iodine in a watery solution of potassium iodide (one part of iodine, three parts of potassium iodide, and four of water). After only a few applications of this solution the condition cleared up permanently. Details are given of another very similar case, and the author suggests that this treatment may be suitable for other forms of tuberculosis of the skin. He points out that the concentration of the solution may be changed to one part of iodine, two parts of potassium iodide, and two parts of water, since a solution as strong as this can still be applied to the skin with impunity. While tincture of iodine has a strong surface action, its deep action is slight. The solution recommended by the author, on the other hand, has but a weak surface action, whereas its deep action is prolonged and strong.

210. Treatment of Chronic Gonorrhoea.

C. Pisacane (*Riv. Sanitaria Siciliana*, May 1st, 1930, p. 611) reports the results of the treatment of twelve cases of chronic gonorrhoea in males with the method of gaseous dilatation recommended by Maisler. The technique used was urethral injection by means of a Guyon's syringe of 1–2 c.cm. of neol (the action of which is similar to that of hydrogen peroxide), followed immediately by 1 c.cm. of silver protein (silver protein 2 grams, glycerin 4 grams, distilled water to 20 c.cm). The production of oxygen dilates the urethra, with consequent compression of its walls, facilitating the penetration of the silver protein into the mucosa. The patients thus

strong, concentrated solution of novocain into the lumbar region of the canal; it sinks towards the coccyx, cutting off the sensory paths and leaving the motor ones unaffected. Müller has treated 30 cases by this method; 4 complained of headache afterwards, and 4 required uterine stimulation. The anaesthesia lasted two and a half hours. Henkel does not consider that the ideal obstetrical anaesthetic has yet been found, nor does he think that in every case an entirely painless labour is desirable. He finds that light ether anaesthesia for the passage of the head is sufficient, since it allows any necessary manipulation and has no bad after-effects.

216. Interstitial Pregnancy.

ALLUDING to the difficulties in diagnosis, before and during operation, caused by interstitial pregnancy, G. COTTE and ARMANET (*La Gynecol.*, March, 1930, p. 129) state that they have twice opened the abdomen for supposed interstitial pregnancy, and have found in the uterine angle a pregnancy which afterwards evolved normally. They quote also the observations of Kreis, who discovered that the site of insertion of the round ligament offers no reliable means of distinguishing interstitial from angular pregnancy. Treatment at operation varies according to the urgency of the symptoms and the age and parity of the patient. When there has been much haemorrhage the choice lies between subtotal hysterectomy and simple resection of the tube; the latter procedure is easier and quicker if the ovary of the affected side is removed at the same time, but haemostasis of the uterine artery demands special care. When the interstitial pregnancy is not complicated by rupture or haemorrhage the same two operations may be envisaged, but in certain cases it is possible to excise the uterine cornu and to implant the remains of the tube in the uterus. Pregnancies have followed cases of resection of a cornu uteri together with unilateral castration.

217. A. BLAGODAROW (*Zentralbl. f. Gynäk.*, April 5th, 1930, p. 868) agrees with others in estimating the proportion of interstitial among ectopic pregnancies as about 1 per cent. He records three cases of interstitial pregnancy, in one of which a pre-operative diagnosis was made. In this case there had been no peritoneal bleeding, and a compact bundle of chorionic villi had penetrated the internal ostium of the tube without having become attached to the endometrium. In one instance the interstitial portion of the tube was lengthened and flexed, and exhibited an acute kink; to such abnormalities Hermstein and Neustadt attach considerable etiological importance. In conflict with earlier writers Blagodarow states that interstitial pregnancy often leads to morbid symptoms before the fourth month, and has not necessarily a bad prognosis.

218. Pregnancy following Nephrectomy.

M. L. PÉREZ and A. I. SOSA Y SANCHEZ (*Rev. Méd. Latino-Americana*, March, 1930, p. 763), who record four illustrative cases, state that pregnancy in a woman who has undergone nephrectomy is a serious problem owing to the risks involved. The favourable character of the prognosis, however, is shown by the fact that among 246 cases with 270 pregnancies there were only 20 complications and 3 deaths. Pregnancy, therefore, after nephrectomy generally pursues a normal course apart from the cause which has necessitated the operation, usually pyonephrosis, nephrolithiasis, or renal tuberculosis. The authors believe that, as a rule, a woman should not be allowed to become pregnant until two to four years after nephrectomy, though in some cases there has been an interval of only one year, and in others nephrectomy has actually been performed during pregnancy. As soon as pregnancy has commenced a close watch should be kept on the patient, so that it should be interrupted if signs of renal insufficiency occur. Lactation is not contraindicated unless the nephrectomy has been performed for unilateral renal tuberculosis. The present four cases were in women aged from 32 to 42, in three of whom nephrectomy had been performed for pyelonephrosis, and in the fourth for obstinate haematuria. In three the renal tolerance was absolutely good throughout pregnancy, and in the fourth there was occasional haematuria. All the women were able to suckle their children without bad effects.

219. Chorea of Pregnancy.

ACCORDING to S. A. SELITZKY (*Gynécol. et Obstét.*, April, 1930, p. 298) the chorea of pregnancy is much more common in northern than southern countries; it is unknown in the Tropics, and very rare in Russia, where only about 20 cases have been reported, 19 in the north. Details are given of eight recent Russian cases. In three there was a personal or family history of infantile chorea, and four patients had albuminuria; one case proved fatal to the mother, and in only three was a live foetus born. Selitzky advises rest, a milk and vegetable diet, and the exhibition of horse serum.

Pathology.

220. Electrically caused Lesions of the Central Nervous System.

THE problem of injuries following contact with electric currents has become an important one owing to the present extensive use of electricity. Circuits supplying homes and factories are commonly of 110 or 220 volts, with either an alternating or a continuous current, and a 100-volt circuit may prove fatal. For this reason O. R. LANGWORTHY (*Journ. Exper. Med.*, June 1st, 1930, p. 943) has deemed it important that a careful study of electrical injuries should be made, and he records experimental evidence concerning the injuries produced in the central nervous system. Many deaths from electricity are attributed to the resulting fibrillation of the cardiac ventricles, and this condition is believed to be more common after contact with low voltage circuits. Circuits at high voltages are thought to cause death from respiratory failure due to a central inhibition in the nervous system. Since in rats the heart recovers spontaneously from ventricular fibrillation, these animals (286 in number) were chosen as the test material, and were exposed to continuous or alternating circuits at different potentials. It was found that these circuits produced different types of lesions in the central nervous system. Haemorrhages were common after alternating current shocks, and few were observed in the continuous circuit group. With both forms of circuits at potentials of 1,000 and 500 volts severe abnormalities in the nerve cells were noted; these were more marked in the continuous circuit group. The Purkinje cells of the cerebellum were most susceptible to the current. Injured cells were studied in the dorsal nucleus of the vagus, in the somatic motor group, among the primary sensory neurones, and in the olivary bodies; the structural cellular changes in reference to recovery are discussed. Injury to the cerebral and cerebellar cortices occurred on the dorsal surface close to the head electrode, and small cavities were produced, particularly in the cerebral cortex, by the circuit contact. With both circuits at 110 and 220 volts potential less severe changes were seen in the nerve cells, although haemorrhages were common in the alternating group. In these cases death was probably due to respiratory blocking rather than to actual death of the cells. While most of the other pathological changes in cells develop slowly, electricity produces abnormalities that may be demonstrated at once, thus indicating the suddenness with which these changes are produced.

221. Lactic Acid Values in Cancer and Hepatic Disease.

O. JERVELL (*Norsk Mag. f. Laegevid.*, May, 1930, p. 536) studied the concentration of lactic acid in the venous blood in 23 patients suffering from various diseases of the liver, and found a rise in the normal amount in 14. Five of these patients had pneumonia and two a cardiac affection which might have been a contributing cause of the excess of lactic acid in the blood. Seven cases, on the other hand, showed no other cause for the excess of lactic acid besides hepatic insufficiency. Normal lactic acid concentration, however, was found in the blood of 9 patients who presented signs of hepatic insufficiency, such as urobilinuria or bilirubinaemia. Of 13 cancer patients, 6 of whom had metastases in the liver, 7 had increased lactic acid concentration in the blood; all the cancer patients, however, were anaemic, so that no definite conclusions could be drawn as to the cause of the excess of lactic acid. In 2 cases, however, in spite of anaemia and hepatic metastasis, normal values were found. Increase in the lactic acid is therefore a frequent though not constant phenomenon in cancer and hepatic disease; its determination does not possess any diagnostic value, and has hardly any prognostic significance.

222. Cardiac Sarcosporidiosis.

G. SCAGLIA (*Arch. Ital. di Anat. e Istol. Patol.*, March–April, 1930, p. 156) examined the hearts of more than a hundred oxen and many sheep in the slaughterhouses at Cagliari at various seasons of the year, and, in spite of the fact that the animals had been in excellent condition, constantly found sarcosporidiosis in a more or less considerable amount in the myocardium generally, and particularly in the bundle of His. Scaglia's own experience, therefore, as well as a study of the literature, indicates that sarcosporidiosis is very frequent in slaughterhouse animals, whereas barely 15, of which the lesions were localized in the heart in a few, have been recorded in the human subject, reported respectively by Hadden (1883), Kiebs (1887), Koch, two cases (1887), Eve (1888), Rosenburg (1892), Kartulio, the only fatal case (1893), Barabau and Saint-Remy (1894), Targett (1899), Darling (1910 and 1919), Brumpt (1910), Manifold (1924), Vasudevan (1927), and Lambert (1927).

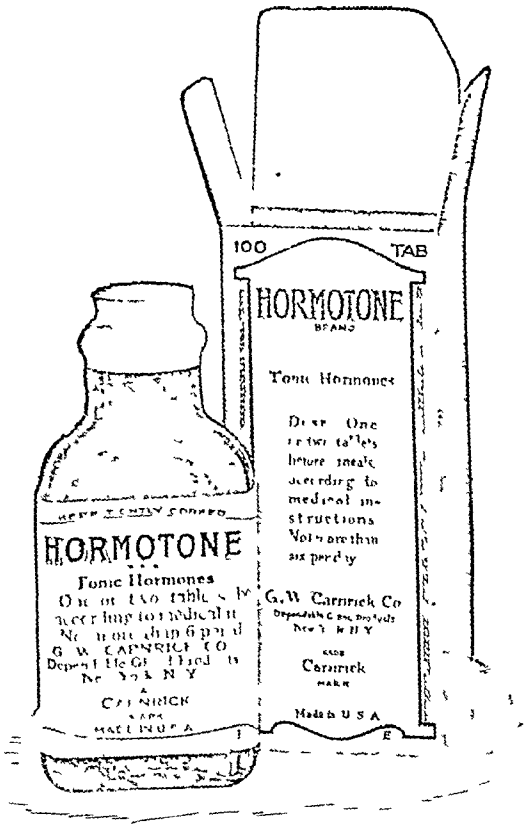
Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.



1. MIDDLESEX.—Rapidly developing district, within 20 miles.—PARTNERSHIP.—A one-half share in an old-estab. good middle-class Practice, averaging for the past two years over £3,500 p.a. Panel of 1,100 and appts. bring in £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.
2. BORDERS OF NORFOLK AND SUFFOLK.—PARTNERSHIP.—A half-share (with succession in 2 to 3 years' time) in a good mixed unopposed Practice, in pleasant village, near two good towns. Income for last 12 months £1,992, including panel of 1,000, and appts. worth about £150. Fees 2/6 to 10/6. House contains 3 reception, 6 bedrooms, etc. Sport of all kinds. Premium 2 years' purchase.
3. HANTS.—Country PRACTICE in very pleasant district. Income for last 12 months £730, including panel of 450. Fees from 4/-. Very good house, with 2 reception, 7 bedrooms, etc. Three acres of garden, etc. Price, freehold, £1,950, part on mortgage. Premium £1,050.
4. PARTNERSHIP.—Within 40 miles of London.—Pleasant Town (pop. over 6,000, with large surrounding district).—A two-fifths share (to commence) is offered in an old-established steadily increasing Practice. Income last year about £1,750, including panel and appts. about £380. Small house available (rent £60) or larger house by purchase (price, freehold, £1,300). Premium only 1½ years' purchase. Excellent future prospects.
5. KENT.—Country PRACTICE, near Coast.—Old-established mixed-class Practice, averaging about £1,100 p.a. Panel of nearly 400. Fees 3/6 upwards. Convenient house, with 3 reception, 6 bedrooms, etc. Good garden. Price for freehold £1,800, £400 on mortgage. Good sport and schools within reach. Premium 1½ years' purchase.
6. LANCS.—Large Town, within easy reach of Manchester.—PARTNERSHIP.—A one-third or one-half share (with succession later) in an old-established good mixed-class Practice, offering large scope. Gross cash receipts for past 12 months £2,645. Panel of over 2,400. Fees 2/6 upwards. Suitable house available, on rental. Premium 2 years' purchase. Ingoing partner must be a Roman Catholic, married, and with Hospital experience.
7. CHESHIRE.—Coast Town, within reach of Liverpool.—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price, freehold, £1,400, £800 on mortgage. Premium 1½ years' purchase, £1,100 down.
8. NORTH OF ENGLAND.—In a small pleasant town, old-established sound PRACTICE averaging over £1,200 p.a., including nearly £500 from panel and appts. Good house (3 reception, 5 bedrooms, bathroom, etc., electric light and every convenience, garage, garden). Price, freehold, £1,300. Mortgage for full amount can be arranged. Premium £1,450.
9. CROYDON AREA.—PARTNERSHIP.—A two fifths or one-third share is offered in a well-established and increasing middle class Practice, averaging £2,600 p.a. (last year £2,740). Panel of 955. Fees 3/6 to 21/-. Midwifery 4 to 15 guineas. Choice of houses. Premium 2 years' purchase, part by arrangement.
10. DEVON.—VILLAGE PRACTICE, situated in very attractive district, within 5 miles of a Hospital town. Receipts for past 12 months £942, including panel producing about £230 p.a. Fees 2/6 to 10/6. Very good ten roomed house, with professional rooms, garage for two cars, cottage, etc. Large garden. Price for freehold £3,000, £2,000 on mortgage. Premium £1,500.
11. SOUTH-WEST OF ENGLAND, within ten miles of coast.—Steadily increasing Country PRACTICE in agricultural district, producing for the past 12 months over £2,300. Panel, with mileage, brings in over £400. Fees 3/6 to 21/-. House contains 2 reception, 5 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Premium £2,800.
12. MANCHESTER.—Chiefly working-class PRACTICE. Average income £1,000, including panel of 1,000. Moderate expenses. Corner House, with 3 reception, 8 bedrooms, etc. Garage Rent on lease £65 p.a. Premium £1,500, or near offer
13. NEAR HUDDERSFIELD.—PARTNERSHIP.—A half share in an old-established mixed-class Practice. Income for immediate past year over £4,250. Panel of 3,500. Fees 3/6 to 7/6. Very good house, with 4 reception, 6 bedrooms, etc. 1½ acres of garden. Price for freehold £2,500. Premium 1½ years' purchase.
14. EASTERN COUNTIES.—Old-established, unopposed, and rapidly increasing Country PRACTICE, in very pleasant sporting and agricultural district, averaging nearly £1,200 p.a. (last year over £1,400). Panel of 500. Very good house (3 sitting, 6 bedrooms, bathroom, etc.). Garden, with tennis lawn. Garage. Electric light. Price, freehold, £2,000, £700 on mortgage. Premium 1½ yrs.' pur.
15. EASTERN COUNTIES.—About 50 miles from London and within 10 miles of county town.—Old-established PRACTICE in pretty country district for immediate disposal, Vendor having accepted an appointment. Receipts average nearly £900 p.a., including panel of 600, and Union £60. Nice house, with ample accommodation, garden, and garage. Can be bought or will be let. Premium 1½ years' purchase, part by instals.
16. PARTNERSHIP.—HOME COUNTY.—Within 40 miles of London.—In small village (with large surrounding population) in very pleasant district, the third share (with option to five-twelfths in 3, and half in 5 years) of old-estab. mixed-class Practice, offering excellent scope. Present income £3,000 p.a., including panel producing over £1,200, and appt. worth £160. Visits 3/6 to 2 gns. Good house at moderate rental. Premium 2 years' purchase, cash. Good society and sport. Ingoing Partner should be about 30, English or Scotch, and married or about to become so.
17. YORKS.—In a clean and thriving manufacturing town, old-established non-panel PRACTICE, partly Homœopathic, and held 50 years by Vendor who is retiring. Cash receipts average about £2,400 p.a. Patients better and middle-class. Midwifery refused. Good house, rent £100 p.a. Premium only 1 year's purchase, part down and balance by arrangement.
18. DERBYSHIRE.—Good mixed-class unopposed PRACTICE, in very picturesque surroundings, within easy reach of good town. Gross cash receipts for past twelve months £900, including panel of 476. Fees 3/6 to 7/6, medicine extra. Suitable house, with 2 reception, 5 bedrooms, etc. Half an acre of garden. Rent on lease £70. Excellent sport and schools. Premium £1,200 or near offer.
19. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). One opponent House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Rent £50 p.a. Prem. £1,400. Excellent sport.
20. YORKSHIRE.—GOOD TOWN.—PARTNERSHIP.—A one-half share (guaranteed to produce £2,000 p.a. in first year) is offered in a good middle-class PRACTICE. Income for the immediate past twelve months approximately £4,000. Small selected panel of 430. One appointment worth nearly £650 p.a. Fees 3/6 upwards. Opposition not strong. Suitable house can be bought or leased. Very good educational and sporting facilities. Premium 2 years' purchase.
21. NEAR HEREFORDSHIRE BORDER.—HOSPITAL TOWN.—Old-estab. lished mainly good-class non-dispensing PRACTICE, averaging about £1,200 p.a. Panel of 500-600. Fees 5/- to 10/6. Nice house in centre of town. Price for freehold £1,200, part on mortgage. Premium £1,800, £1,300 down and balance by instalments. Up to-date Cottage Hospital, and good scope for surgery.
22. YORKS.—PARTNERSHIP.—Within a few miles of large residential town, the half share of old-established unopposed country PRACTICE, owing to retirement of senior partner through age and in different health. Cash receipts for past three years average over £2,500 p.a., including appointments and panel of 1,200. Very little midwifery. Railway station. Good house available, with large garden. Electric light and water laid on. Price freehold £1,200, part on mortgage. Premium 2 years' purchase.
23. PARTNERSHIP.—COUNTY TOWN, within 130 miles North of London.—A one-fifth share is offered in a very old-established good mixed-class Practice having good scope. Gross cash receipts for past twelve months nearly £6,000, including panel of 3,400. Fees from 4/-. Not much midwifery. Suitable house available. Prem. 2 yrs.' pur.
24. WEST OF ENGLAND.—In a small pleasantly situated town amidst beautiful surrounding country, old-established PRACTICE. Income nearly £1,350 p.a., including panel of 900. Visits 5/- to 21/-. Little midwifery. Very attractive house in own grounds of 2 acres, 3 large professional rooms (separate entrance), 2 reception, 5 bedrooms, bathroom, etc. Vendor's freehold. Price £2,400 (£1,800 can remain on mortgage). Premium £2,000. Good society, etc.
25. LANCS.—Pleasant Town, near open country.—Well-established middle- and better-class PRACTICE. Cash receipts last year over £980, including panel of 900. Visits 3/6 to 7/6, medicine extra. Mid. 2 to 10 gns. (about 20 cases). Suitable house, with 2 reception, 4 bedrooms, etc. Price for leasehold £1,100, £600 on mortgage. Premium 1½ years' purchase, part by instalments.
26. GLOS. — COUNTRY PRACTICE. — Old-established PRACTICE in picturesque surroundings, averaging about £1,250 p.a., including panel of over 1,100. Visits from 3/-. Commodious house, with 3 reception, 6 bedrooms, etc. Garden. Garage. Price for freehold £1,500, £1,000 on mortgage. Premium £1,850.
27. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
28. LANCS.—LARGE TOWN.—Old-established good working-class PRACTICE, averaging about £2,500 p.a. Panel of over 1,800. Fees from 2/6. Suitable house available. Premium 1½ years' purchase.
29. SOMERSET COAST.—PARTNERSHIP.—In a small increasing seaside resort, the five-twelfths share of a very old established PRACTICE, producing last year £1,600, but offering exceptional scope. Panel brings in £480, and appointments. Visits 5/- to 4 gns. Mid. 4 to 6 gns.; only about 12 cases yearly. Choice of 2 suitable houses (price freehold £950), with gardens. Electric light and gas. Premium 2 years' purchase.
30. SOUTH OF ENGLAND (Thriving Seaport Town, pop. over 30,000).—Old-established mixed-class PRACTICE. Income last year £623, but offering exceptional scope. Panel of about 430 and 2 small appts. Visits 3/6 to 5/-. Very attractive residence, with professional rooms, 2 reception, 4 bedrooms, bathroom, etc. Pretty garden. Garage. Rent on lease £100 p.a. Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands after their extirpation from healthy animals. . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922)

[illegible] of the BRITISH MEDICAL JOURNAL is this week 39,250 copies.

them, before he enters a university or medical school, he must be prepared to spend an extra year at the medical school. He must in a sense start a year behind the men of his year. A student who has completed chemistry and physics, but not biology, may be handicapped by time-table difficulties.

The position is emphasized at Oxford and Cambridge, where medical students have an opportunity of taking a degree with honours in natural science. For the examinations for these honour degrees there is a time limit of terms from matriculation, so that a student who has to devote his first year at the university to First M.B. subjects is handicapped a whole year in competition with men who are able to start preparation for an honours degree in their first term. In some cases students after leaving a public school spend a year at the medical school of a London hospital in order to pass the First M.B. Examinations of the University of Cambridge, and then proceed to Cambridge in the following year. Boys who intend to study medicine are usually advised to complete the work of the First M.B. or a similar examination before they enter a university or medical school; that under present conditions the advice is wise none can doubt.

One result is that the general education of the medical student stops at a very early age; while he is still very young he specializes on the science side of his school, and begins to cram for a series of pass examinations in elementary science. A boy of ability can pass an examination which entitles him to matriculate at a university or enter a medical school between his fifteenth and sixteenth birthday. In too many cases the passing of the matriculation examination means the end of general education. It may be argued that a boy who can pass one of these examinations has proved that he has had a good education. A boy who can just pass a university matriculation examination has attained a reasonable but not remarkable standard of general knowledge. But the point is that boys destined for professions other than medicine continue their general education for one, or two, or perhaps three years after they have passed a matriculation examination. The medical student loses two or three years, and the best years of his life at a public school, the years spent in the upper forms of the classical or modern side. There are still some who hold, as the author of this article holds, that a classical education—the discipline of the Greek and Latin tongue—is the best training for science, and for every other profession. But among those who will not go so far as this there may be some who will admit that a knowledge of literature and language, and the power to express thought clearly in speech and writing, are far from negligible assets to the scientist and the medical man. We are proud to think that we belong to a learned profession, and we have sanctioned a system which tends to put a premium on illiteracy.

On the other hand, it may be doubted whether the schoolboy gets good value for the last two years of his school life if he devotes them almost entirely to First M.B. subjects. It has been said often enough that natural science is better appreciated at the university than at the school age; under the aegis of a university department rather than in the form room of a public school. There may be something in this point of view, although it must be admitted that not all university teaching has the quality of inspiration, and science is excellently taught in many schools. But it is true that preparation for the First M.B. takes longer at school than it does at a university. Preparation for the First M.B. at school occupies about two years, and school terms are longer than university terms. A certain number of boys after two years of science at school are unable to pass the First M.B.; they have, however, done enough to become bored, and they have lost their interest in science.

One of the great difficulties which confront the schoolmaster is the fact that each university has a separate schedule and syllabus for its First M.B. Examination; this difficulty is marked in the case of biology. In the case of the matriculation examination universities accept one or other of the examinations conducted by the joint university examination boards, and the schoolmaster can choose one examination for all his pupils. It is difficult for a schoolmaster to prepare a number of boys in one class to meet the varied requirements of the First M.B. Examination of a number of universities. If boys are expected to pass the First M.B. from school, the universities should agree to form a joint examination board to provide a common First M.B. Examination.

There has been a tendency to raise the minimal age at which a student may be admitted to a university or medical school; nevertheless, we allow schoolboys, aged 15, to begin preparation for professional examinations. The study of natural science at school is one thing, the assimilation of knowledge with the immediate object of passing an examination is another. On the other hand, it has become very difficult for a boy to remain on the classical side of a public school until he is 18 or 19, and then begin the medical curriculum after he has matriculated at a university. Thirty years ago many students entered a laboratory for the first time in their first term at a medical school. To-day a boy who has postponed the commencement of science until he enters the university is at a great disadvantage as compared with his contemporaries, and must work very hard to catch up. It seems a pity that the choice of medicine as a career must be made so early. It is a serious matter if the medical profession is to lose recruits who have had the great advantage of a general and unspecialized education. If preparation for the First M.B. must be undertaken at school the syllabus of the examination should be so framed or cut down that the necessary work should not occupy more than the last year at school.

The Medical School.

The chief characteristic of the medical curriculum is the lack of co-ordination between the various subjects of which it is composed. The curriculum may be divided into three stages or strata: (1) the elementary study of physics, chemistry, zoology, and botany; (2) the more intensive study of human anatomy, and physiology; (3) the practical study of the recognition, prevention, and treatment of disease. Between these three principal strata are two huge clefts, and numerous subsidiary fissures divide the subjects included in each stratum.

The effective control of each subject remains with the professor or head of the department, but, as a general rule, professors of chemistry, physics, zoology, and botany are not medical men. The attitude of the professor of chemistry, for example, towards the faculty of medicine is perfectly clear, perfectly logical. From time to time, in one medical school after another, the medical faculty or one of its members, greatly daring, asks the professor of chemistry, "Could you manage to adapt your First M.B. course to the needs of the medical student?" The professor of chemistry replies, "Do you want your medical students taught chemistry, or do you not?" The answer is "Yes." "Very well," retorts the professor of chemistry (and who will blame him?), "I know what chemistry is and you do not; I settle the syllabus." In practice the conversations are more polite and protracted. The attitude of the professor of chemistry is not unreasonable, and it is not easy for the medical man to explain to the chemist the needs of the medical student.

Occasionally the professors of pure science are more complacent, and meet their colleagues of the faculty of medicine more than half-way. A professor of chemistry has said, "We teach the medical student the structural formulae of all the more important drugs." A professor of physics remarks: "I quite understand; you want the medical student to know about the physics of the *x*-ray coil." A professor of zoology proposed to include in his elementary course for medical students an account of the structure and life-history of parasites. These examples are quoted to show how difficult it is for non-medical teachers to understand the needs of the medical student. The technical applications of science must come later; the medical student in his first year needs the fundamental principles of the natural sciences. His labours are lightened when his teacher can abstain from examples which illustrate the applications of science to other trades and professions.

If his mind is not made up already, the newly qualified practitioner has now to consider in which branch of the profession he can find a suitable outlet for his energies. The choice is very wide, though (as in many other affairs of life) the decision is often dictated rather by opportunity than by a nice balancing of tastes and talents. Among the great variety of paths open are general medical practice in town or country; Government service at home or abroad, including, of course, the medical branches of the Navy and Army and Air Force, and the I.M.S.; public health appointments and other administrative or official posts; institutional work, such as that of the municipal hospital, the mental hospital, the fever hospital, and the sanatorium; academic positions in the various schools of medicine; and special work in scientific research or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in the later sections of this Educational Number, but a few words may be said here about general practice and the work of a consultant or specialist.

Further information about such matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.[1] This comprises articles on openings for members of the profession; on practical aspects of medical work; on registration and the privileges of practitioners; on practice under the Insurance Acts; on post-graduation study and special diplomas; and on medical defence societies. The section dealing with practical aspects of medical work embodies much sound advice on professional conduct, on common medico-legal difficulties, and on the relations between doctor and patient and one doctor and another.

GENERAL PRACTICE.

It is estimated that three-quarters at least of those who pass out of the medical schools become "family doctors" sooner or later. The work is onerous and the pay too often inadequate; but it is a full life rich in human interest, and many of the very best students, now as formerly, choose general practice as a career. It is usually entered in one of three ways. The newcomer may take a house, put up a plate, and wait for work to come to him; he may buy the goodwill of a practice rendered vacant by retirement or death; or he may become a partner in an established firm. The first is considered more risky than the second, and the second than the third. A well-managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy. Those who begin their work as assistants seldom find cause to regret the time spent in learning the ropes under the eye of an experienced senior. As the circumstances of general practice vary much from place to place, it may be well to serve this "post-graduate apprenticeship" under conditions resembling those to be met later.

The general practitioner cannot hope to be an expert in every department of medicine, but he should have a more comprehensive outlook than the man whose life is devoted to perfecting himself in the technique and minutiae of one subject, to which he gives all his energy and time. Both types of workers are indispensable. It says, they are complementary. The good general practitioner possesses powers of perspective in disease that are denied to the specialist, and he must remain not only the most useful and encyclopaedic working unit of our profession, but also the member of it to whom, at least in the first instance, the public, for its own good, should apply for relief in sickness and guidance in maintaining health. The opportunities he has of seeing his patients repeatedly for minor ailments as well as for serious illnesses; his acquaintance with their idiosyncrasies, their family history, habits of life, and social circumstances; and many other personal details learnt only after long and confidential intercourse, make the "G.P.," of all medical men, the most important. In short, he has just that knowledge which enables him to treat the patient and not merely the disease.

The value of the work done by the family medical attendant is better appreciated now than in the past. In its recent Proposals for a General Medical Service for the Nation[1] the British Medical Association puts this matter in the forefront. It states as an axiom that "the medical service of the community must be based on the provision for every individual of a general practitioner or family doctor"; and the whole series of proposals rests on this as a fundamental principle. In regard to the prevention of disease, on which the Association lays great stress in its memorandum, the general practitioner has an increasingly important part to play. Unlike the doctor of yesterday, his time is not now wholly spent in treating developed disease in individuals. As knowledge accumulates he will come more and more to study early disorders of function and the preservation of bodily and mental health in varying circumstances. While this is all to the good, it cannot be denied that encroachments on private medical practice are perpetually being made under the auspices of the State or of the municipality or of voluntary bodies, and that official requirements and administrative checks imposed by public authorities tend to increase.

The national system of compulsory health insurance, now more than eighteen years old, has had a profound influence on general medical practice in this country. The Insurance Acts provide domiciliary medical attendance for some sixteen million persons, and more than 17,000 members of our profession undertake responsibility for the medical care of this vast section of the community. Thus the bulk of the general practitioners of the country now give, in large or small measure, medical attendance and treatment under a system embracing almost the whole working population. These practitioners, by placing their names on the panel (or medical list), signify their assent to the terms of service set out in the Medical Benefit Regulations and other relevant provisions. It would have been strange indeed if a measure so far-reaching and so complex had not brought about great changes in general practice, with some detriment to the freedom of the individual doctor. On the other hand, the panel system admittedly gives a better service than was provided under the old "club" arrangements, though it is by no means as complete or as effective as it might be made.

CONSULTANT AND SPECIALIST PRACTICE.

The term "consulting practice" comprises in ordinary usage the work of the general physician, that of the general surgical consultant or operating surgeon, and that of the gynaecologist and obstetrician. These are the three large divisions of consulting practice, as distinct from general practice, which, though they imply some restriction, yet call for a wide range of activity and outlook, in contrast with the smaller ambit of a "specialty" in the narrow sense. Of these main divisions the third is obviously the most limited, but on several grounds it can claim to rank as something larger and more comprehensive than the other specialties. It is impossible, however, to draw a sharp line between consulting practice and specialist practice. Most general consultants, whether medical or surgical, are specialists in some branch of their practice,

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES.

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College of Swansea. He must also hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or a B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years; the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year, and in medicine, surgery, obstetrics, and gynaecology in December also.

The university also offers courses of study in public health and in tuberculosis. Candidates for the diploma in public health (D.P.H.) and for the tuberculous diseases diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff, or at another institution approved by the university.

WELSH NATIONAL SCHOOL OF MEDICINE

Students can complete the whole of their curriculum in the Welsh National School of Medicine, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

English Medical Corporations.

THERE are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD

THIS body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in public health, tropical diseases, ophthalmic medicine and surgery, psychological medicine, laryngology and otology, and gynaecology and obstetrics—jointly issued by the two Colleges in question. Under the present regulations every candidate for the L.R.C.P. and M.R.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in the Educational Number of the *British Medical Journal* for 1922, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

PRESENT REGULATIONS FOR THE CONJOINT DIPLOMAS.

The following is an outline of the present regulations for the L.R.C.P.Lond. and M.R.C.S.Eng. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

PRE-MEDICAL EXAMINATION.

Students are required to pass a pre-medical examination in chemistry, physics, and elementary biology, conducted by the Conjoint Examining Board, before commencing the five years' curriculum of professional study, or some other examination recognized by the Board—namely, the examination in chemistry, physics, and biology for the degree in Medicine of any university recognized by the Board, the higher school certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the higher certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, the Central Welsh Board higher certificate, or the pre-medical examination in chemistry, physics, and biology conducted by any of the qualifying bodies whose degrees or diplomas are registrable on the *Medical Register*.

A candidate must enter for chemistry and physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required preliminary examination in general education.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. Not more than two terms of professional study is recognized before the examination in elementary biology is passed.

PROFESSIONAL EXAMINATIONS.

There are two professional examinations called the First and Final Examinations. The courses of study for the First Examination may be commenced before the pre-medical examination in chemistry and physics or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

First Professional Examination.—The subjects of this are: Section I, (*a*) Anatomy, including histology and embryology; (*b*) physiology, including biochemistry. Section II, Pharmacology, practical pharmacy and materia medica. A candidate must have attended at a recognized Medical School courses of instruction in anatomy, including embryology, during five terms, in the course of which he must dissect the whole body, courses of instruction in physiology, including general biology, biochemistry, and biophysics during five terms, courses of instruction in pharmacology and materia medica. A candidate may present himself for the two sections together or separately, but he must take parts (*a*) and (*b*) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are: Section I, Pathology (including morbid anatomy, morbid histology, and clinical pathology) and bacteriology. Section II, Part I, Medicine, including medical anatomy, forensic medicine, and public health; Part II, Surgery, including surgical anatomy and the use of surgical appliances. Part III, Midwifery and gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately, or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. No exemption is granted from any subject in the Final Examination.

are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts, science, or medical degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Service, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £256, the separate examination fees included in this calculation being as follows:

	£	s.	d.
First Professional	9	9	0
Second Professional...	7	7	0
Third Professional	6	6	0
Final	11	11	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews, information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

THE CARNEGIE TRUST.

The following is a summary of the regulations made by the Carnegie Trust for the Universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 17 years of age; they must be of Scottish birth or extraction, or have attended for two years, after the age of 14, at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department, provided that it bears evidence of such preliminary education as is required by the universities for their graduating curricula, or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies, and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained, and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years, in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are: Arts and Medicine—two Arts grants of £3 and four Medicine grants of £19, in all £22; Science and Medicine—two Science grants of £17 and four Medicine grants of £19, in all £110.

Applicants, in writing for application forms, must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session, or May 10th for the summer session. Payments are made by means of fee coupons, and fees already paid are not refunded.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board, which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P.Ed., L.R.C.S.Ed. and L.R.F.P.S.Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect three Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £83. Further information can be obtained from Mr. Walter Hurst, Faculty Hall, 242 St. Vincent Street, Glasgow.

Irish Universities and Corporations.

MEDICAL REGISTRATION IN THE IRISH FREE STATE.

The Medical Practitioners Act, 1927 (Irish Free State), provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council will be (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the register and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty on the advice of the Privy Council, to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts, and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the general *Register* formerly vested in certain universities and medical corporations in Ireland, are not affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general *Register* the General Medical Council and the Branch Council for Ireland shall have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general *Register* shall be entitled on the payment of a prescribed fee to be registered in the *Irish Free State Register*, but this fee will not be payable by any person who on the date of the establishment of the *Irish Free State Medical Register*, is registered on the general *Register*. Then follow provisions with regard to the erasure from the *Register* of the name of a person on account of misconduct.

The *Irish Free State Medical Register* was established on May 26th, 1928, this being the date appointed by the Medical Registration Council. The *Register* on establishment contained the names of every medical practitioner who was registered in the general *Medical Register* immediately before May 26th, 1928, and who either was then resident in the Free State according to his address as stated in the general *Register*, or was living outside the Free State and applied to the Council within one month before May 26th, 1928, to be registered. No fee for registration was charged in such cases.

For registration in the *Irish Free State Register* subsequent to its establishment a fee is required, together with a prescribed form of application. A person is eligible for registration if he is at the time of application registered in the general *Medical Register*, or if he possesses the requisite qualifying diploma granted by colleges or bodies in the Free State as set out in the Act. Application for further information may be made to the Registrar, Medical Registration Council, Room 35, Upper Fitzwilliam Street, Dublin.

THE IRISH UNIVERSITIES.

There are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland; and, in Northern Ireland, the Queen's University of Belfast.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants post-graduate diplomas in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who, having passed the professional examination, have also graduated in arts.

PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific.—This covers (*a*) chemistry, (*b*) physics, (*c*) botany and zoology; the three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (*a*) anatomy, physiology, organic chemistry, and histology; (*b*) applied anatomy and applied (clinical) physiology. The two parts may be taken separately or together.

Final Examination.—Part I. Hygiene and medical jurisprudence, pathology and bacteriology, materia medica and therapeutics. Part II. (*a*) Midwifery and gynaecology; (*b*) medicine and mental diseases; (*c*) surgery in all branches, including clinical ophthalmology. The three sections of Part II. may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and also examine him viva voce on other medical subjects of a more general nature.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing and have been engaged in practice for two years.

M.A.O.—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in the study of obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND

The Diploma in Public Health

Every candidate for the Diploma in Public Health must observe the following rules:

Rule 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health.

Rule 2. The curriculum for the Diploma in Public Health shall extend over a period of not less than two calendar months, and shall conform to the attainment of a registrable qualification.

Rule 3. Every candidate shall produce evidence of having attended during a period of not less than four months at an institution approved by the Licensing Body granting the Diploma, practical instruction in—

(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man,
(*b*) Chemistry and Physics in relation to Public Health,
(*c*) Meteorology and Climatology in relation to Public Health.

At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical laboratory work.

At least 90 hours must be devoted to Course (*b*), of which no less than 70 hours shall be occupied in practical laboratory work.

At least 10 hours must be devoted to Course (*c*).

Rule 4. Every candidate shall produce evidence of having received during not less than 80 hours at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects:

(*a*) The Principles of Public Health and Sanitation (30),
(*b*) Epidemiology and Vital Statistics (20),
(*c*) Sanitary Law and Administration (including Public Medical Services) (20),
(*d*) Sanitary Construction and Planning (10).

[The numbers indicate the normal proportion of time to be given to each subject.]

Rule 5. Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases, and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

Rule 6. Every candidate shall produce evidence that he has, during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of Public Health Administration under the supervision of a Medical Officer of Health, who shall certify that the candidate has received from this Officer or other competent Medical Officer, during not less than three hours on each of sixty working days, practical instruction in these duties and also those relating to

(*a*) Maternity and Child Welfare Service,
(*b*) Health Service for Children of School Age,
(*c*) Venereal Diseases Service,
(*d*) Tuberculosis Service,
(*e*) Industrial Hygiene,
(*f*) Inspection and Control of Food including meat and milk.

Certificates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who devotes his whole time to Public Health work, or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50 000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50 000.

Rule 7. The examination for the Diploma shall be divided into two parts, Part I and Part II.

Rule 8. The examination for Part I shall include the following subjects:

Bacteriology and Parasitology (including Medical Entomology),
Chemistry and Physics, and Meteorology and Climatology in relation to Public Health.

Rule 9. The examination for Part II shall include the following subjects:

Hygiene and Sanitation (including Sanitary Construction),
Epidemiology and Infectious Diseases,
Sanitary Law and Vital Statistics,
Public Health Administration.

The examination shall be written and oral, and shall include practical examinations in Infectious Diseases, Food inspection, Inspection of premises—dwellings, factories, workshops, schools, etc.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

THOSE whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of the Royal College of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College.

Fees.—For the Licence in Medicine 15 guineas. Special Examination, £21. For the Licence in Midwifery, 8 guineas. Special Examination, 16 guineas. For the Membership 20 guineas to a Licentiate of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND

THIS body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology, and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce, while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*, if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination which sum if the candidate is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

Fees.—Primary Examination (Parts I and II) £21. Final Examination £21. Subjects of examination: Primary Part I, Anatomy and Physiology; Primary Part II, Materia Medica including Pharmacy, Medical Jurisprudence and Hygiene, Pathology. Final Examination, Medicine, Surgery, and Midwifery. Candidates must enter for and pass at the one time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate times, but the Final Examination cannot be completed until a period of three years has elapsed from the date of passing Primary Examination Part II.

Application for other information should be made to the Registrar, 95 Merrion Square, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all or them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St Pancras, in the County of London

received treatment. Of the latter number, 39,226 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the paediatric, orthopaedic, venereal, radiological, electro- and physico-therapeutical, and inoculation departments. The number of major operations which were performed amounted to 7,422.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time director, assisted by an assistant director, two assistants, and two house-physicians, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of obstetrics and gynaecology there are two assistants and two resident accoucheurs. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. Two resident hostels are provided for the convenience of students and the holders of house appointments. Recent additions to hospital and college buildings include a laboratory for the manufacture of certain preparations of radium. The athletic ground, of over thirteen acres, is at Higham's Park, and is open to all members of the Clubs Union

Appointments.—The salaried appointments, open to past students of the hospital are those of assistants to the medical unit, first assistants to the medical and surgical firms; obstetric registrar, assistants to the department of obstetrics and gynaecology, medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin orthopaedic, and electrical departments, and in the Institute of Pathology There are appointed annually 4 resident accoucheurs, 14 resident house-physicians and 22 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes.—The following is a list of scholarships and prizes:—At entrance: Price Scholarship in science, £100. Two open scholarships, each of the value of £100. Scholarships open to students of Oxford and Cambridge Universities (1) £100, anatomy and physiology; (2) £100, pathology. Entrance Scholarship in science, £50; Epsom Scholarship, "free medical education." After entrance: Burton Prize in anatomy and physiology, £40; Letheby Prizes in organic chemistry and chemical pathology, £25; Prizes in clinical medicine, surgery, and obstetrics and gynaecology, £20 each; Duckworth Nelson Prize in practical medicine and surgery, £10; Hutchinson Prize in clinical surgery, £60; Treves Prize in clinical surgery, £15, Sutton Prize in pathology, £20; K. E. D. Payne Research Scholarship in pathology, £20; Sir Andrew Clark Prize in clinical medicine and pathology, £14; T. A. M. Ross (proxime accessit) Prize in clinical medicine and pathology, £10 10s; Anderson Prizes in elementary clinical medicine, £20, Dressers' Prizes, £20; Practical Anatomy Prizes, £10; Arnold-Thompson Prize in medical and surgical diseases of children, £15; Liddle Prize, £120; Francis Farmer Entrance Scholarship in chemistry and physics, £25, Harold Fink Prize in dental surgery, £8 8s. The "London" Prizes in dental surgery and pathology, £5 5s., and in dental prosthesis, £5 5s. Seven class examination prizes, each of the value of £3 3s., are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in medical research.

Fees.—Entrance fee, 20 or 15 guineas, according to examinations passed; annual fee, 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

THE MIDDLESEX HOSPITAL.

THE school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goodge Street, and Great Portland Street stations. There are a gymnasium, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for mental cases, for cases of venereal disease, and for diseases of children and of the skin and eye. The newly built west wing and residents' house are now occupied.

The medical school, which includes the Bland-Sutton Institute of Pathology, the S. A. Courtauld Institute of Biochemistry, and the Barnato-Joel Laboratories, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute, under the charge of the Professor of Pathology, contains large pathological and public health laboratories, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The Biochemical Institute is under the charge of the Professor of Biochemistry, and contains teaching and research laboratories in addition to those devoted to the routine clinical work of the hospital. The Barnato-Joel Laboratories offer unrivalled opportunities for the study of cancer in both its clinical and pathological aspects

Appointments.—Twenty-six resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense Two casualty medical and two casualty surgical officers, and three resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination, six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. Ten registrars are appointed annually In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases, dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and post-mortem clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odonto-logical, children's, and electro-therapeutic out-patient departments.

Scholarships.—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships, of the value of £90 and £60 respectively, are open to students of the Universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25, Hetley Clinical Prize,

Fees.—First year (First M.B. or pre-medical course), £36 15s.; second and third years, £42 each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

St. Mary's Hospital.

THIS hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 348 beds, and extensions recently completed have provided two new operating theatres. By a scheme of affiliation, for teaching purposes, of several neighbouring hospitals, the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the courses of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Wembley, and can be reached in twenty minutes by a constant service of trains.

Clinical Facilities.—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St. Mary's being one of the six medical schools in London which enjoy this privilege. Under this system professors of medicine and surgery, with competent assistants, give their whole time to teaching and research. This means a regularity of teaching and a degree of individual attention that are only possible where units exist. The system also provides additional salaried posts which are open to students after qualification.

Teaching of Midwifery.—The hospital has lying-in beds, and in addition to the instruction thus obtained each student attends a short course at Queen Charlotte's Hospital as part of his training in midwifery, without additional fee. Under the new building scheme it is proposed to institute additional lying-in wards.

Institute of Pathology and Research.—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute, and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the medical school, including ten salaried posts, with salaries varying from £200 to £750 per annum.

Rebuilding of the Medical School.—The site for the rebuilding of the medical school and inoculation department has already been cleared, and building operations will be commenced shortly. The new school will contain departments for the teaching of all preliminary and intermediate subjects, and will include a students' club, dining and billiard rooms, and a gymnasium and swimming bath.

Complete Curriculum.—The medical school provides complete courses of instruction, and students can join at once on passing a preliminary examination in arts. Terms begin in October, January, and April.

Entrance Scholarships.—Two Entrance Scholarships of £210 each and one of £26 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarships. The Geraldine Harmsworth Scholarship (£200) and one or more University Scholarships of £200 are awarded annually in July.

Fees.—Composition fees for entire curriculum (6 years), £205 in one sum, or £215 by five annual instalments. Composition fee for clinical curriculum (3 years), 95 guineas in one sum, or 100 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas, with an entrance fee.

St. Thomas's Hospital.

THIS school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. St. Thomas's House, the new Students' Club recently opened, comprises spacious dining and club rooms, etc., and provides accommodation for some sixty resident students. The terrace affords facilities for exercise and recreation. The sports ground, more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. Clinical units in medicine and surgery have been established. The maternity ward, containing 21 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician and a resident assistant surgeon at £225 each per annum, and a resident anaesthetist at £200 per annum, are appointed annually. Eight hospital registrars—three medical, one diseases of children, and four surgical—at an annual salary of £250 each, rising by £25 to £300, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding three years. A pathological registrar to the department of obstetrics and gynaecology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £200), and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Seven house-physicians (including two obstetric house-physicians and one house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose, and throat department) are appointed every six months. Thirty-six or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five Entrance Scholarships: one in arts, giving two years' free tuition; one of £150 and one of £60, in chemistry, physics, and biology, for students who have not received instruction in anatomy or physiology; one of £100, and an exhibition worth £40, in any two of the following subjects: anatomy, physiology, chemistry, or pathology, for students who have completed their examinations in anatomy and physiology for a medical degree in any of the universities of the United Kingdom or the Colonies, and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, medicine, pathology, and hygiene; (*e*) Wainwright Prize, medicine; (*f*) Toller Prize, medicine; (*g*) Cheselden Medal, surgery and anatomy; (*h*) Clutton Memorial Medal in clinical surgery, biennial; (*i*) Beaney Scholarship, £50 biennially, surgery and clinical pathology; (*j*) Solly Medal and Prize, biennially, reports of cases; (*k*) Sutton Sams Prize, biennially, reports of cases, (*l*) Bristowe Medal, pathology and morbid anatomy; (*m*) Hadden Prize, pathology and morbid anatomy; (*n*) Grainger Testimonial Prize, £31 10s., anatomy and physiology; (*o*) Louis Jenner Research

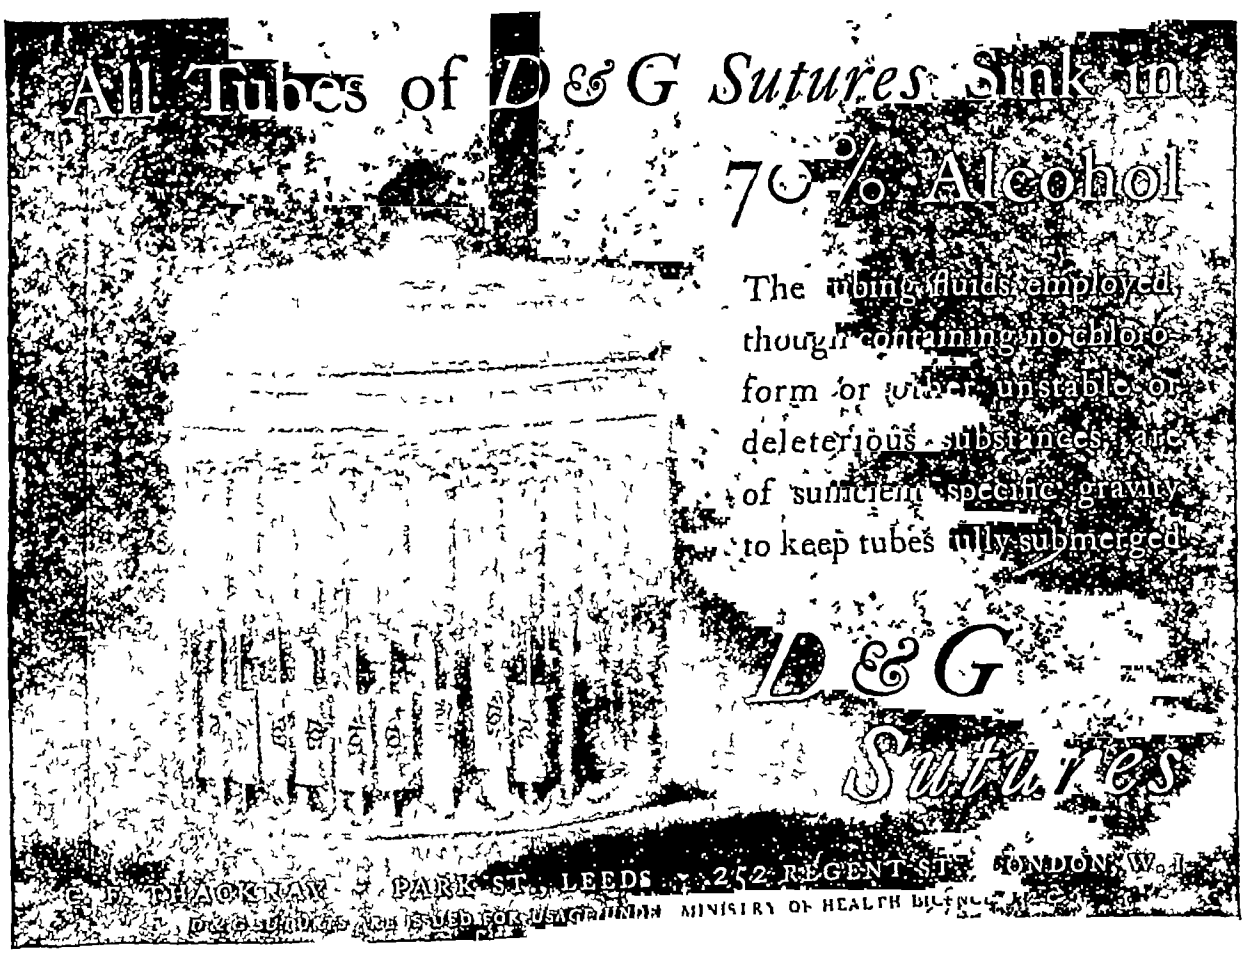
INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17, Park Lane, London, W 1 The fees for a room cost now only two guineas a week, interest in the project having made possible a series of four reductions since the scheme was started

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses and yet at the same time to avoid any semblance of a charity which would be distasteful to such)

(The only condition attaching to the endowment is that any advantages—such as they are—should be widely advertised and not in any way limited to any small section of the community A further promise is made that if, and as, more beds are required they will be provided)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane
Telephones Grosvenor 2312 & 2313



A Typical Scale of Reduced Fees for Surgical Cases in the Annexe Clinic of the Harold Fink Memorial Hospital at 17, Park Lane

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6 6 0
Dressings, Theatre Fees, etc	1 1 0
Anæsthetic Fee	3 3 0
Surgical Fees for Major Operation (nominal fee only according to patient's means) (say, from)	10 10 0
(From Twenty guineas inclusive fee)	£21 0 0

The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant who may of course be present at the operation, and who, if convenient to himself, will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in Chief (with a view, for example, to a Bismuth Meal, Cystoscopic, X-ray Examination etc), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made (Proportionately reduced nominal fees only charged therefor)
Telephones Grosvenor 2312 & 2313

All rooms are of course separate, and hold one patient only, there being no wards

and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union Room, and refectory are provided for the use of students. Resident accommodation for 80 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 268 beds, all of which are available for clinical instruction. The obstetrical and gynæcological unit controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, children and infant welfare, venereal diseases, orthopædic surgery, massage, light, electrical and x-ray work, dentistry, and casualty. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Horton Mental Hospital, Epsom; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, Great Ormond Street, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the Medical School and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynæcological, and medical registrars, assistant pathologists, assistant anæsthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship, value £30, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, the Alfred Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50, and the Mabel Sharman-Crawford Scholarship, value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years, the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years, and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Bostock Scholarship, value £30 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Julia Ann Hornblower Cock Prize of £60, the Helen Prideaux Prize of £60, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £16 a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Post-Graduate Scholarship of £100 is awarded annually. Altogether the school offers annually £1,350 in scholarships. Various missionary societies also offer scholarships on certain conditions, and assist women who wish to go to India and other countries as medical missionaries.

Fees.—Courses for the University of London degrees and the diplomas of the Conjoint Board in England and other qualifications £50 per annum throughout the course.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

KING'S COLLEGE

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to one of the associated or other hospitals to pursue their studies for the final examinations. Special courses in anatomy and physiology are held in preparation for the primary examinations for the Fellowship of the Royal College of Surgeons.

A course for the degree of the University of London and for the diploma of the Royal College of Surgeons in dental surgery is given in conjunction with King's College Hospital Medical School.

Scholarships.—The entrance scholarships are (1) Two Warneford Scholarships, each £30 for four years, subjects—selected from mathematics, classics, divinity, and science; (2) One Sambrooke Scholarship of £30 for three years, subjects of examination selected from mathematics, classics, and science. The holders of the preceding awards must proceed to King's College Hospital; (3) Worsley £100, paid in five annual instalments; (4) Rabbeth Scholarships, value £30 and £15, in July, for the best student of the first year; (5) Donnell Scholarship, £40, awarded on the results of the University Honours Examination; (6) The Layton and Berridge Studentships, each £150 per annum, and (7) numerous prizes.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science, King's College, Strand, W.C.2.

UNIVERSITY COLLEGE.

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy (including embryology and histology), physiology, biochemistry, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing and for about seventy women students at Byng Place, Gordon Square.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 160 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), two entrance exhibitions in the same subjects, each of the value of 55 guineas, a Faculty of Medical Sciences Entrance Scholarship value £30 a year for three years, and the Baynes Starling Memorial Scholarship (physiology and or biochemistry), £120.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London, W.C.1.

THE PROVINCES

There are in England and Wales, not counting London, ten medical schools each supplying instructions in the full medical curriculum. Accounts of these here follow. In several cases information is appended about hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

THE LONDON & COUNTIES MEDICAL PROTECTION SOCIETY, Ltd.

VICTORY HOUSE, LEICESTER SQUARE, LONDON, W.C.2.

President Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., F.R.C.P., F.R.S.

OBJECTS.—To protect, support and safeguard the characters and interests of legally qualified Medical and Dental Practitioners to advise and assist Members of the Society in matters affecting their professional characters and interests. *UNLIMITED INDEMNITY* is provided to Members (subject to the Articles of the Association) against the costs of actions undertaken for them by the Society and against adverse costs and damages awarded against them in such actions.

SUBSCRIPTION £1 PER ANNUM. ENTRANCE FEE 10s. *Telephone* REGENT 0611.

Those who join within one year of Registration are exempt from Entrance Fee.

ments, £60 per annum; dental house-surgeon (non-resident), £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £40, open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medal for fifth year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Rouse Scholarship for proficiency in diseases of the nose, throat, and ear, or skin, value £17; Lady Haberfield Scholarship, value about 25 guineas; Bristol and Bath City Scholarships and the Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Dorset, etc., are tenable in the university.

Some of the Fellowships awarded by the Colston Research Society for research in the university are allotted to the Faculty of Medicine.

A Bowlby Fellowship tenable for three years is open to all members of the university holding a medical qualification.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

Further information as to scholarships, curricula and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-upon-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university. Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, where there are facilities for the study of the various special subjects. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, and has an annual indoor and outdoor attendance on 3,000 cases. In the Heath wing of the school itself there is a gymnasium and a set of rooms for the separate use of the students. A new bacteriological department has been erected adjacent to Armstrong College.

Post-Graduate Instruction.—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary, and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

Students' Union.—A Students' Union has been erected and furnished at a cost of over £40,000, and is in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments.—Pathological assistants, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

Scholarships.—University of Durham Entrance Scholarship, £25 a year for four years; Pears Entrance Scholarship £40 a year for three years (awarded every third year), Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable), Province of Durham Masonic (Entrance) Scholarship, £60 (renewable), Heath Scholarship for surgery, £200 available every second year, Rutherford Morison Surgical Scholarship, £180, available every third year.

The following scholarships are tenable for one year—namely, Tulloch Scholarship for elementary biology and organic chemistry, £20, Dickinson Scholarship for medicine, surgery, midwifery, and pathology, Gold Medal and £20, Charlton Scholarship for medicine, £25, Gibb Scholarship for pathology, £23, Luke Armstrong Scholarship for comparative pathology, £25, Stephen Scott Scholarship for surgery, £40, Philipson Scholarships for highest marks in Final M.B., B.S. Examination, two of £48 each, Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325, Gibson Prize for midwifery and diseases of women and children, £10, Turnbull Prize and Silver Medal for surface anatomy, Outterson Wood Prize for psychological medicine, £10, and Sewell Memorial Prize and Silver Medal for clinical pathology. At the end of each session a prize of books is awarded in each of the regular classes.

Fees.—The composition fee for lectures at the college is £140. Composition fee for hospital practice, £46, *plus* £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Dean of the College, University of Durham College of Medicine, Newcastle-upon-Tyne.

LEEDS

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, well-arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and museums of pathology and anatomy. The comfort of the students is secured by means of common rooms and a refectory. Extensions of the medical school buildings will be opened in October, 1930, and an Institute of Pathology is to be built in the near future on an immediately adjacent site. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, special children's wards, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, have 88 beds. The West Riding Mental Hospital at Wakefield is available for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—Physicians' clerks and surgical dressers are appointed every six months, clerks in the children's department, orthopædic dressers, ophthalmic and aural dressers, gynæcological ward clerks, maternity clerks, assistant physicians' clerks, dermatological clerks, assistant surgeons' dressers, dressers in the casualty rooms, junior and senior post-mortem clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation a considerable number of resident and other appointments become available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships.—The university awards annually on the results of the first examination a scholarship in the form of free admission to the lectures and classes given in the School of Medicine. The university also awards a scholarship on the results of the second examination, of the value of £68, in the form of free admission to the clinical teaching of the infirmary.

Fees.—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £324 *plus*, of course, the expenses of living during the five and a half years covered by the curriculum. The composition fee for the course for the first, second, and third examinations, and for the clinical work at the infirmary is £237. The composition and clinical fee for those who have passed the second examination is £156.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine, Leeds.

LIVERPOOL

THE Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which a list is given below, have amalgamated to form the clinical school of the university.

It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, and that no responsibility is accepted with regard to the accuracy of the statements therein contained

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies

connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms for both men and women students. There are also two student unions—one for men and one for women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopædics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anæsthetics is given at either institution by the anæsthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Mental Hospital.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships.—Entrance Medical Scholarship, value about £100, open to both sexes. Six Edgar Allen Scholarships of £125 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees' Scholarships, each of the value of £50 a year, tenable for three years for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50 a year, for boys or girls under 19 years of age educated in any school in Sheffield, secondary or otherwise. Town Trustees Fellowship, value £75, tenable for one year. Mechanics Institute Fellowship, value £50 (with remission of fee), tenable for one year, and renewable for a second year. The Fredrick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £36 for each of the first five years and £25 6s. 8d. for the sixth year. The composition fees for the dental courses are as follows: for B.D.S., first and third years, £75, second, fourth, and fifth years, £25, for L.D.S., first and second years, £75, third and fourth years, £25. The fee for special courses taken separately can be ascertained by inquiry of the Dean. (*Note.*—The fees for the session 1931–32 will be increased.)

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

THE WELSH NATIONAL SCHOOL OF MEDICINE.

THE next session opens on October 7th. All classes are open to both men and women students. Particulars relating to the admission of students as from October 7th, 1930, can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport Road, Cardiff.

The following is a list of heads of departments: Physics, Professor (to be appointed), chemistry, Professor W. J. Jones; zoology, Professor W. M. Tattersall, botany, Professor R. C. McLean, anatomy, Professor C. McLaren West; physiology, Professor T. Graham Brown, materia medica and pharmacology, Dr. W. Mitchell Stevens, pathology and bacteriology, Dr. J. B. Duguid; medicine, Professor A. M. Kennedy, surgery, Professor A. W. Sheen, obstetrics and gynæcology, Professor Sir Ewen J. Maclean, preventive medicine, Professor Edgar L. Collis; tuberculosis, Professor S. Lyle Cummins.

SCOTLAND

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for post-graduation work.

ABERDEEN

THE school is conducted by the Faculty of Medicine. This comprises thirteen chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and preparatory), chemistry (ordinary and preparatory), anatomy, physiology, materia medica, pathology, bacteriology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and infectious diseases, tropical medicine, medical ethics, tuberculosis, and clinical methods are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 370 patients), the Royal Mental Hospital (200 patients), the Sick Children's Hospital (132 patients), the City Fever Hospital (350 patients), the General Dispensary, Maternity, and Vaccine Institution (10 000 out-patients annually), and the Ophthalmic Institution (3 000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital, in fevers at the City Fever Hospital, in mental diseases at the Royal Mental Hospital, in diseases of the ear, nose, and throat at the Infirmary and Dispensary, in diseases of the eye at the Infirmary and Eye Institution, in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.). A diploma in public health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty.

Bursaries, scholarships and fellowships, to the number of fifty, and of the annual value of £1,200, may be held by students of medicine in this university. They range from £8 to £150 per annum and are tenable in most cases for two or three years. The winter session begins on October 14th, 1930; the summer session on April 21st, 1931.

Fees.—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 35 guineas. The total cost including hospital fees, class and matriculation fees and degree fees is about £242.

EDINBURGH

THERE are two Schools of Medicine, the School of the University, and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium and Museum; zoological laboratory and museum of science and art; physical laboratory; chemical laboratories, dissecting room, bone room, and anatomical museum; physiological laboratory; medical jurisprudence laboratories; John Usher Institute of Public Health, materia medica museum and laboratory; post-mortem department of the

In addition, the following bursaries, scholarships, and prizes are open to students prosecuting their studies in the Faculty of Medicine: Arbuthnott Bursary, annual value £40, tenable for three years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. Arthur Bursary, annual value £20, tenable for three years, awarded to the *women* student who takes the highest place among the Queen Margaret College candidates at the First Professional Examination. Mary Allan Bell Bursaries (five), annual value £50 each, tenable for three or four years, for students who have gone through the curriculum in arts; special examination, tenable also in theology or law. Brisbane Bursary, annual value £50, tenable for four years; candidates must be under 22 years of age, and must have taken the degree of M.A. William Gardiner Bursary, annual value £18, tenable for two years, awarded on results of the First and Second Professional Examinations in the subjects of physiology, chemistry, and physics. Dr. Thomas Gibson Bursary, annual value £50, tenable for four years; open to medical students entering on their second winter who are preparing for service as *medical* missionaries. Johnston Bursaries (two), annual value £25 each, tenable for three years, for eminence in the work and examinations of the first and second years of the curriculum. Lorimer Bursaries (six), value £20 each, tenable for one year, are awarded to the best students in each of the following classes—botany, zoology, physics, chemistry, anatomy, physiology. Macfarlane Bursary, annual value £40, tenable for three years, for students who have attended the first session of their professional study in the university, examination in elementary anatomy, elementary chemistry, and botany. Mackintosh Bursary, value £31, tenable for one year, open to medical students of either sex who have attended one of the courses of lectures on insanity; examination in that subject. John Monteith Bursary, annual value £21, tenable for two years, is awarded annually to the student who gains the highest number of marks in the subjects of anatomy and physiology at the professional examinations held during the previous year. Ramsay Bursary, annual value £50, tenable for two years, for students entering on their third session of medical study; awarded to the candidate whose aggregate of marks in the subjects of anatomy and physiology of the Second Professional Examination, and in chemistry, botany, and zoology of the First Professional Examination, is the highest. A. and B. Stewart Bursaries, annual value £50 each, tenable for three years, for students who have gone through the arts curriculum, there is a special examination. Walton Bursary, annual value £40, tenable for four years; the Earl of Sandwich has the right of appointing to the bursary one of two students nominated by the Senate. Weir Bursary, value £25, tenable for one year, awarded on the results of the Second and Third Professional Examinations. Barbour Scholarship in anatomy or physiology, annual value £250, tenable for two years. Joseph Coats Memorial Scholarship, value £35, tenable for one year, for research in pathology, may be held concurrently with the Perman Memorial Scholarship (q.v.). Faulds Fellowship, annual value £250, tenable for three years, for medical research. Foulis Memorial Scholarship in pathology, value £50. Four McCunn Medical Research Scholarships, value £200 each, tenable for one year. Perman Memorial Scholarship, value £50, tenable for one year, for research in pathology, may be held concurrently with the Joseph Coats Memorial Scholarship (q.v.). The Junior Arnott Prize of about £15, the Senior Arnott Prize of £25. Three Bellahouston Gold Medals. The Brunton Memorial Prize of about £20. The Macewen Medal in surgery. The Captain H. S. Rankin V.C. Memorial Prize of £4 10s. The Straits Settlements Gold Medal. The West of Scotland R.A.M.C. Memorial Prize of about £15.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*, and summarized at page 363 of this issue. Scholarships and Fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study.

Fees.—The matriculation fee for each year is £2 12s. 6d. In most cases the fee for each university class is £6 6s., but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s. for a perpetual ticket, or £1 11s. 6d. for a single term ticket, with an additional fee of £5 5s. for each winter and £2 12s. 6d. per term for each clinical course. The fees are the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £259.

For further information apply to the Registrar, Glasgow University.

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading rooms, library, etc. They are taught in some classes apart from male students, in most together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary; also *inter alia* in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel, Hawkhead Asylum, the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarships.—The Arthur Scholarship, annual value £20 tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1931. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Queen Margaret College, Glasgow.

Board for Students.—University houses of residence for women students, Queen Margaret Hall and Roberts Hall, are situated near the college. The cost of board and residence is from 35s. to 42s. a week, according to accommodation. Applications to be made to the Wardens. Another hostel near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board is from 32s. to 35s. weekly. Applications to be made to the Warden.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) 782 beds, 542 for surgical and 240 for medical cases. There are special beds and wards for diseases of women, of the throat, nose, and ear, burns, and septic cases. In the out-patient department in 1928 over 97,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion with the latest and most improved apparatus for diagnosis and treatment.

Appointments.—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The *fees* for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86 Castle Street.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar).

Fees.—The fees for the lectures and practical work required by ordinary students range between 2 and 6 guineas a session. The Carnegie Trust pays the *fees of students* at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with 160 beds, offers facilities for clinical instruction in the diseases peculiar to women. A university lectureship, the Royal Samaritan Lectureship in gynaecology, is associated with the hospital. The lecturer is Dr. David Shannon.

Medical and Scientific Stationers,

136 GOWER STREET LONDON W C.1

to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) two Musgrave Studentships of £200 in physiology and pathology. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £200. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Bursar, Queen's University, Belfast, price 4d.

University College, Cork.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (130 beds), the County and City of Cork Lying-in Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well-equipped dental hospital in connexion with the school.

Scholarships.—About £3,000 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £170.

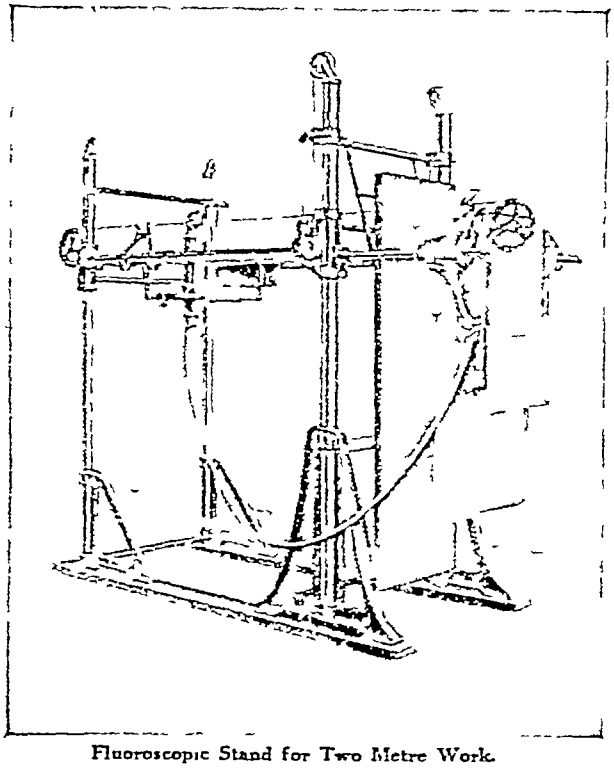
Further information can be found in the Calendar or obtained on application to the Registrar.

University College, Galway.

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of the London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £2,500 and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND.

Many hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year, or even longer. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities; but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; the Derbyshire Royal Infirmary; South Devon and East Cornwall Hospital, Plymouth; the Royal Albert Hospital and Eye Hospital, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton, the Norfolk and Norwich Hospital; the General Hospital, Nottingham, the Royal Portsmouth Hospital, the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital, the Staffordshire General Infirmary, Stafford, the North Staffordshire Infirmary at Hartshill, the Royal Hants County Hospital, Winchester, the Wolverhampton and Staffordshire General Hospital, the County Hospital, York; and the Coventry and Warwickshire Hospital.



London Clinical Hospitals.

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 268 beds. There are also the East London Hospital for Children, Shadwell, with 156, the Queen's Hospital for Children, Bethnal Green with 134, the Victoria Hospital for Children, Chelsea with 130, the Belgrave Hospital for Children, which has a considerable out-patient department and in-patient accommodation for 74 children, the Paddington Green Children's Hospital, and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women, Waterloo Road, S.E.1.

Hospitals for Women.—Queen Charlotte's Maternity Hospital, Marylebone Road, with 75 beds and a residential college for medical students and practitioners, specializes in the teaching of midwifery. The first section of the new Queen Charlotte's Hospital in Goldhawk Road, Hammersmith, was opened on July 10th last. The City of London Maternity Hospital, City Road, with 71 beds, also admits medical students and graduates to its practice. The Samaritan Hospital for Women, Marylebone Road, admits qualified practitioners as clinical assistants to both the in-patient and out-patient departments, demonstrations are given daily in both departments, the fee—payable in advance—being £3 3s. for three months, full particulars may be obtained from the Secretary. In addition may be mentioned the Hospital for Women, Soho Square, where teaching is confined to post-graduates in limited numbers, the Chelsea Hospital for Women, Arthur Street, Chelsea, and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road, E.C.1, 152 beds; 2,534 in-patients, 51,924 out-patients in 1929. At this hospital two complete courses of instruction are given during the year—October to February, and March to July—comprising the following subjects: (1) anatomy (including histology and embryology), (2) physiology, (3) optics (including physiological optics), (4) refraction classes, (5) methods of examination and use of the ophthalmoscope, (6) pathology and bacteriology, (7) ophthalmic medicine and surgery, (8) ophthalmoscopic conditions, (9) operative surgery, (10) practical pathology, (11) practical bacteriology, (12) radiology, (13) physiotherapy (including ultra-violet light, diathermy, and ionization), (14) slit-lamp microscopy. A fee of 35 guineas will

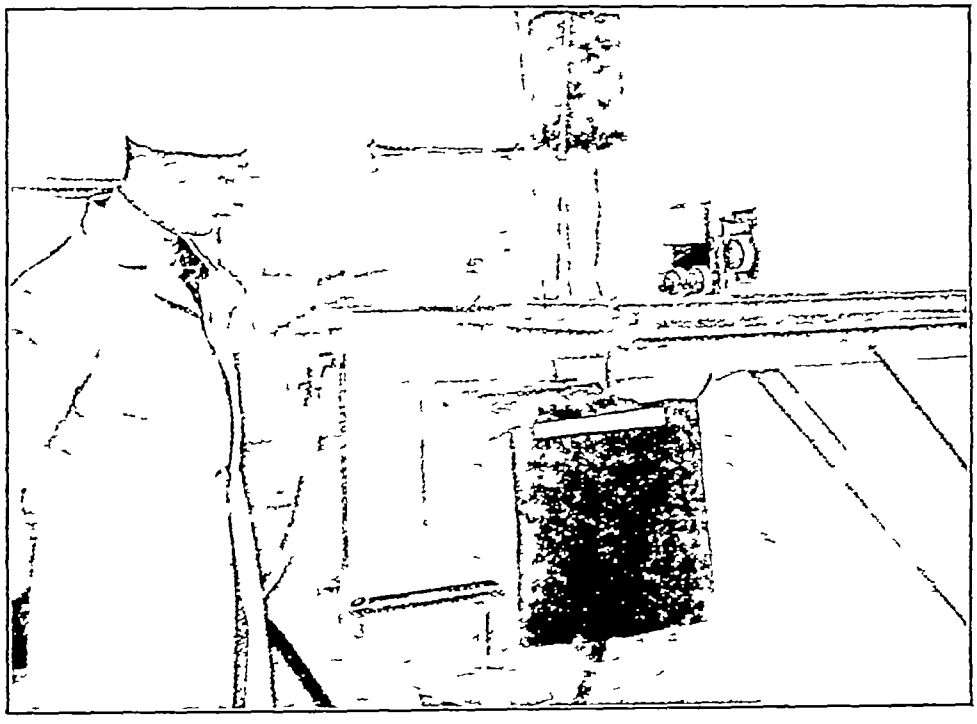
SCARCELY MORE THAN TWICE THE PRICE

of ordinary window-glass

The question of cost has often proved an obstacle against the acceptance of new methods Before a steady demand had been created for "Vita" Glass prices were necessarily high



But the new stabilised prices open up vast possibilities for the use of windows that admit health as well as light "Vita" Glass now costs scarcely more than twice the price of ordinary window-glass but it converts windows into channels of health instead of shutters against it Its properties are guaranteed permanent Over 300 hospitals and nearly 200 schools are now fitted with "Vita" Glass Employers are using it more and more in offices and factories and it is being fitted daily in private houses all over the country Write for full particulars to the "Vita" Glass Marketing Board, 9 Crown Glass Works, St Helens, Lancashire

"Vita" Glass is obtainable through local Glass Merchants, Plumbers, Glaziers and Builders

"VITA" GLASS

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

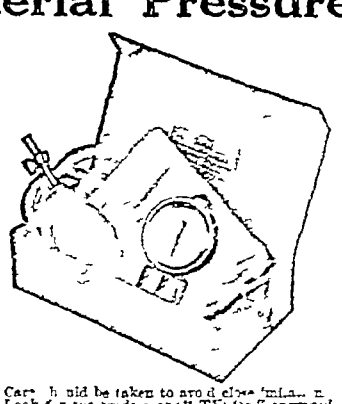
THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted a banking account offers Perhaps it is assumed that to conduct an account by post involves more letter writing', or is costly or is not welcomed by the Bank It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method and offers some clear suggestions



The Secretary of the Bank will be pleased to send a copy on application

WHEN VITALITY IS LOW, THEY STIMULATE AND CREATE A DESIRE FOR SOLID FOOD

BY APPOINTMENT

A RECENT investigation revealed that as many as 99 *out of every* 100 doctors interviewed are recommending Brand's Essences for their patients in serious illness and convalescence

Consisting only of the pure essences of the finest fresh meats, conserved in their natural form, they can be rapidly absorbed without the slightest strain on the digestion No substances are added which would prevent easy assimilation, such as colouring matter, gelatine, or preservatives

During that period in serious illness when a patient's vitality is at its lowest, these Essences never fail to restore energy quickly

And in convalescence, when the very idea of food is repugnant, Brand's Essences bring back the appetite — prepare the patient for more solid diet.

OUT OF EVERY 100 DOCTORS RECENTLY INTERVIEWED, 99 RECOMMENDED

BRAND'S ESSENCES

(Made only from the finest English Beef Chicken or Mutton)

Brand's Essences are obtainable at chemists and stores throughout the world in small and large-sized tins and glasses Samples will be sent you gladly on receipt of a professional card Write Dept F8 Brand & Co Ltd., Mayfair Works, Vauxhall, S W 8

MARSHALL'S Lysol helps the district nurse

THE district nurse and her neat bag are welcome in thousands of homes where pain or disease have claimed a victim Dressings come out of her bag and simple remedies, but the thing that comes out most often is a brown bottle of Marshall's Lysol For the district nurse knows that for a slight abrasion or a serious wound Marshall s Lysol is the SAFE and certain antiseptic.

Marshall's Lysol is unequalled in quality because it is the only Lysol made from the original formula and specification Every bottle is of the uniform fine quality that has made Marshall s Lysol famous throughout the medical profession

Marshall's Lysol really is an efficient and reliable antiseptic and is absolutely harmless when used as directed, but must never be used undiluted

Kalzana promotes Calcium Retention

The value of Kalzana tablets lies in their combination of calcium lactate and sodium lactate. In the body the sodium lactate becomes converted into sodium carbonate and imparts the requisite alkalescence to the blood which is necessary to ensure calcium retention. The reports of eminent physicians show that Kalzana possesses all the advantages which one may expect from a calcium preparation.

"The Practitioner" says.

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium particularly because Kalzana promotes calcium retention"

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil completely overcomes this objection. By combining calcium acetyl salicylate with Alocol' unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract.

"Alasil" is therefore a triumph over acetyl salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, Alasil is indicated in all cases where acetyl salicylic acid has been used heretofore.

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

Health Aspects of Vita-Weat

In cases of diet regime a readily acceptable and beneficial alternative to ordinary bread will be found in Vita-Weat—the whole-wheat British crispbread

The "Lancet's" Report.

Being made from 100% stone-ground whole wheat, Vita-Weat preserves all the vitamins intact The *Lancet* reports that Vita-Weat is "a valuable foodstuff, more particularly in respect of its content of Vitamin B" Vita-Weat is also rich in Vitamins A and D, in proteins, and in the valuable mineral salts so necessary to health

Extremely Palatable.

Vita-Weat is extremely palatable, possessing a delicious "crunchiness" and ripe-corn flavour Its crispness encourages mastication and so promotes a healthy condition of the teeth and gums

High Calorie Value

"The calorie value of Vita-Weat," says the *Practitioner*, "is 2,132 per lb, which may be compared with the calorie value of fresh white bread, namely 1,210 per lb" It will thus be seen that Vita-Weat possesses a high physiological fuel value.

To Counteract Constipation

The branny scales of Vita-Weat act as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane

To Prevent Obesity.

The starch granules in Vita-Weat are thoroughly disintegrated No starch passes unconverted into the body to cause obesity and indigestion Vita-Weat is "completely assimilable," states a report of the Royal Institute of Public Health

Streptococcal Conditions

In the treatment of Streptococcal conditions Vaccines provide the surest means of reaching deep-seated organs which are inaccessible to antiseptics Some practitioners, however, are deterred from using Vaccines owing to fear of reactions, but this objection may be overcome by employing Detoxicated Streptococcal Vaccine (Genatosan) In the preparation of this vaccine all the toxic elements of the germ are removed, as a result it is given in both acute and chronic cases without harmful reactions and produces a high degree of immunity

For the average case a course of five injections is recommended, commencing with an initial dose of 1,000 millions and working up to a maximum of 20,000 millions Detoxicated Streptococcal Vaccine is polyvalent and is suitable for the treatment of septicæmia, puerperal fever, cellulitis, lymphangitis, and all septic infections of streptococcal origin

Practitioners interested in Vaccine Therapy are invited to write for a brochure covering the full range of Detoxicated Vaccines, to Genatosan Ltd (Vaccine Dept), Loughborough, Leics

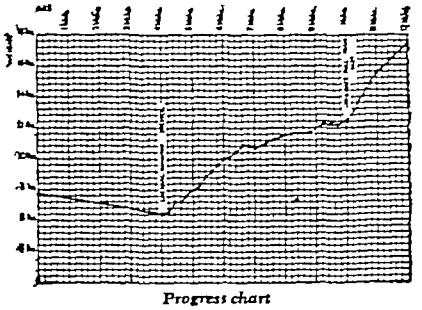
A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia The infant was put on to LACIDAC (Separated) with a small quantity of BRESTOL and immediately made steady progress



At 6 months he had gained 3 lbs 7 ozs and by the end of another 4 months his weight was 12 lbs 6 ozs, and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby

His Doctor considers him a '*Resurrection.*'

BEFORE—*4 months' old 6 lbs. 9 ozs. in weight*

Progress chart

AFTER—*10 months old 12 lbs 6 ozs. in weight*

June, 1930 Baby "H" has now won a prize in a Baby Show!

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient*

Benger's Food is prepared with fresh cows' milk It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing The process may be arrested at any time by simply bringing the mixture to the boil (A useful average time for standing is 15 minutes)

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

NEW YORK MONTREAL SYDNEY CAPE TOWN MILAN BOMBAY SHANGHAI BUENOS AIRES

SAINT JOHN CHRYSOSTOM PATRIARCH OF BYZANTINE CONSTANTINOPLE AND A GREAT PIONEER FOUNDER OF HOSPITALS.—The most important Byzantine contribution to progress in the domain of medicine was the widespread building of hospitals and the organisation of the care of the sick and necessitous. St. Chrysostom was one of the foremost workers in this field. He built a number of hospitals and leper houses not only in Constantinople but in Antioch and perhaps elsewhere in the empire, paying for them at first out of his official salary and later with the aid of sympathisers such as the rich lady Olympia who left him the whole of her wealth for this purpose. Under the system inaugurated by St. Chrysostom, the various categories of the necessitous were provided for in separate buildings. Thus the NOSOCOMIUM received those suffering from acute diseases; cripples and chronic invalids were cared for in LOBOTROPHIA; while the XENODOCHIUM was designed for the treatment of sick travellers and pilgrims. The BREPHOTROPHIA were foundling hospitals; orphans were housed and brought up in ORPHANOTROPHIA; and the old were succoured in almshouses or GERONTOCOMIA.

The Morison Lectures

ON

NERVOUS SEMEIOLOGY, WITH SPECIAL REFERENCE TO EPILEPSY

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH ON JUNE 2ND, 3RD, AND 4TH, 1930,

BY

S. A. KINNIER WILSON, M.D., F.R.C.P.,

NEUROLOGIST AND LECTURER IN NEUROLOGY, KING'S COLLEGE HOSPITAL.

LECTURE I.—THE RELATION OF NERVOUS SYMPTOMS TO NERVOUS LESIONS

IT is my first and pleasing duty to express to the President and Council of the Royal College of Physicians of Edinburgh my deep appreciation of the signal honour paid me by the request to deliver the Morison Lectures. Scanning the list of my distinguished predecessors and the subjects chosen by them, I find that comparatively few have in recent years dealt with any special aspect of neurology, and I am glad to take this chance of submitting to the consideration of my *confrères some matters bearing on nervous* semeiology and on the interrelation of nervous symptoms and lesions to which I have long given thought. I do this with no little diffidence, however, because the general considerations to the importance of which I have become increasingly attached will doubtless appear to a number familiar and possibly axiomatic, yet they may prove not without interest as representing, in some degree, certain changes in my own views on fundamental problems of interpretation that concern every neurologist. There is also advantage in allowing one self the leisure for a look round, seeing that the directional flow of a stream is not always appreciated by *those whose attention is centred* on eddies, pools, or backwaters.

As a tyro in the subject of nervous diseases I imagine I began with a conception based on clinical differentia, it seemed practical enough to separate cases in accordance with their particular semeiology, a given disease was represented clinically by a corresponding syndrome or symptom-complex, and even if *specific modifications* were found the generic picture could always be relied on for purposes of diagnosis. The typical syndrome of disseminated sclerosis was constituted by the old Charcotian triad of intention tremor, nystagmus, and scanning speech, that of tabes by Argyll Robertson pupil, lightning pains, ataxia, and loss of deep reflexes; of infantile paralysis by flaccid palsies, wasted muscles, and deformities, and so forth. Yet it did not take long to be convinced of the limitations of a purely clinical arrangement, for the fact was soon discovered that one and the same symptom can arise in conjunction with lesions at different physiological levels in the nervous system, *and as a result of different pathogenic actions*. Besides, experience showed the futility of the endeavour to circumscribe the clinical tableau of a given affection by a series of Procrustean lops. Epidemic encephalitis may be thought by some to be one and indivisible, but so far as its semeiology is concerned its manifestations are legion.

The next step, *under the influence of honoured teachers* of twenty-five years ago, was to rely on the well-tried clinico-anatomical method, to correlate symptoms during life with lesions found after death and to assume (if not always to demonstrate) their essential consonance. I am the last person to decry the value of the method in a time, for there can be no doubt, in the first place that such correlation (with certain provisos) is legitimate enough, and *in the second*, that its employment has led to discoveries and advances of the first importance. Indeed I suppose the devotees of what has been called the neurological school of medical thought are as numerous as ever and will continue to be reinforced by successive generations of medical students unless and until their preceptors are sufficiently emboldened to point out its rather misleading assumptions. The method, if I *mistake not*, is becoming just a little *démodé*, although years have already elapsed since that shrewd observer the late Sir James Goodhart wrote a paper on 'The passing of morbid anatomy,' which exercised more than a transient influence on my own views. *Hopeful lines of present-day research* are directed to study of the living in preference to scrutiny of the dead, and some day diagnostic autopsies will be a reproach and not a satisfaction.

It appears to me incontrovertible that neither a clinical nor a pathological classification offers any particular advantage from the standpoint of nology and that the only basis for the scientific arrangement of nervous diseases is etiology. Yet this is precisely the department of investigation which lags behind. The enumeration of a large group of nervous affections is undiscovered, but until we find interesting factors we dare not begin to speak of such and such *a clinico-pathological combination as constituting a disease*. The day has passed for the physician to transform clinical syndromes and pathological complexes into diseases. For what is a disease? Obviously it is neither the etiological excitant nor the clinical *allure* nor any underlying pathological change, *and we may* with Sir Humphry Rolleston allege that it is nothing else than a mental picture—a conception figured in the mind, a composite of elements no one of which by itself suffices to define. At any rate, we shall find great may insuperable, difficulty in establishing disease entities unless we can prove that a given causative agent produces invariably and solely the same reaction *in the body*, exhibiting the same syndromes, and amenable to the same treatment.

THE PHYSIOLOGICAL NATURE OF SYMPTOMS

1. It will, I think, be generally allowed that an etiological factor, a pathogenic agent, can be regarded physiologically as a stimulus, and physiology recognizes only three classes of stimuli—namely, pure excitants, pure depressants and those which first excite and then depress. Accordingly, clinical symptoms are to be considered as representing either excitation or cessation of function or a series in which the latter follows the former. *Without exception*, all are functional, *in the sense* of being related to *function*. To attempt to distinguish "functional" from *organic* symptoms is therefore meaningless. This *so far as I personally am concerned, is an ancient platitude. I date my* awakening to a conversation with *my old teacher the late Dr. Charlton Bastian* who *when I told him* a patient had been admitted under his care *suffering from* what I with the dogmatism of the *house-physician*, described as functional fits," *replied*. "Did you ever see a fit that was not functional?" I then secured an insight into semeiology which I trust I have never since failed to maintain. Whether we deal with motor, sensory, vegetative, or psychical symptoms, each and all are classifiable as consisting of either increase (inclusive of "escape") of function, or of decrease, and there is nothing else.

2. A symptom is the expression of a physiological reaction, and hence can never be specific unless we imagine

reactions themselves to be so—an impossibility when the unbelievable diversity of stimuli is born in mind. Take any banal symptom of neurology—headache, neuralgia, hemiplegia, paraplegia, amyotrophy, anaesthesia—everyone recognizes their production by a host of differing agencies. With advance of knowledge the alleged specificity of many a neurological symptom is steadily undermined, till we may well question whether any at all can thus be distinguished. An Argyll Robertson pupil is just as characteristic of colloidal neoplasm as of neurosyphilis, the epileptic fit occurs as a semeiological incident in circumstances we should never dream of ascribing to a "disease" called "epilepsy", intention-tremor is by no means confined to the subjects of disseminated sclerosis. I have not myself seen a case of rabies, but no one who is conversant with the graphic descriptions of older observers can fail to notice either the remarkable similarity of recorded cases as regards the dramatic consequences of any attempt to swallow fluids, or the overwhelming consensus of opinion that such symptoms are so pathognomonic of the disease as to provide it with one of its names. Here, however, is a recent account, reported by Fletcher and Fitzpatrick[1] in the *Lancet* of 1927:

"When he attempted to swallow the result was terrible. While we were examining him he asked for some iced water, but no sooner did he put the cup to his lips than he was seized with violent spasms of the throat, jaws, and left side of his face. The small amount of fluid which had entered his mouth was shot out again with a hissing sound. Short, sharp hisses followed each other at intervals of about half a second. With each hiss the head was jerked forward by a spasm of the sterno mastoids, and sometimes the hiss ended in a sharp sound like a bark. The patient must have remained in this torture for a minute or more," etc.

No feature of the spasms of hydrophobia is awanting, not even the bark, the case, however, was one of tetanus. Further comment would surely be superfluous.

3. Being the expression of a process (of excitation or depression, as the case may be) a symptom is likely to be fluctuating and variable, it may wax and wane, rise and fall, it need not be the same at each examination, and therefore any argument that "organic" can be differentiated from "functional" symptoms by their relatively unchanging character, or their persistent nature, or their being uninfluenced by factors of a different order, is at once vitiated. The tremor of paralysis agitans is as patently under the influence of emotional and other psychical stimuli as is that of hysteria, it may be present at one moment and absent the next (an observation made originally by James Parkinson[2] himself). A number of illustrations of this clinical fact were given in the Croonian Lectures[3] of 1925. Similarly, in cases of progressive lenticular degeneration I have had occasion to observe the remarkable "fluidity" of the tremor, which may leave one group for no apparent reason to develop forthwith in some other, separate, distribution. The tremor of hysteria, in point of fact, does not often itself exhibit such variability. Only when a structural change is permanent, when tissue reaction has come to an end, does a given symptom become stabilized or static. In itself it stands in no constant relationship whatever to underlying structural alterations. Thus may we observe a patient with disseminated sclerosis exhibiting ankle clonus one week and none the next, but even more illustrative instances are at hand. In the course of the cataplectic attack of narcolepsy the knee-jerks are abolished as completely, as "organically," as in a case of tabes with sclerosis of dorsal columns—yet only for a few seconds or minutes. One of my narcoleptic patients at hospital, a girl of 18, fell sound asleep in the ophthalmic room after I had been looking at her discs, during this sleep tapping her patellar tendons yielded one single, brief, and faint twitch, and thereafter they were totally irresponsive to repeated percussion, yet when she awoke, walked into another room, and sat down, the knee-jerks were found again to be brisk. Recent work by Jacobson[4] in the University of Chicago has proved that a normal subject may so relax himself voluntarily, may empty his muscles of tone to such a degree, that in the course of a few minutes the knee-jerks may be entirely abolished. I had occasion to sit by the bedside of an old gentleman of 70, who complained of recurring attacks of right-sided weakness, on my first examination he showed neither symptom nor sign of abnormality but while I was talking to him he suddenly remarked 'It's coming back now," and a minute later he could move neither arm nor leg. I then found a characteristic extensor plantar response where a moment before it had been flexor, and the abdominal reflex disappeared. Ten minutes later, power returned, and once more the plantar reaction was in flexion.

From these and numerous examples that come to mind, which can surely be paralleled in the experience of most neurologists, I submit only one conclusion can be drawn—namely, that symptoms *per se* are the expression of dynamic alterations in function, and either may *or may not* coincide with structural change. To ascribe of necessity to structural lesions what we have been in the habit of thinking "organic" signs is therefore improper, only when the latter are residual and static is it legitimate to attribute to them such clinical phenomena. Otherwise, indeed, our talk of "recovery of function" is meaningless. A further conclusion is, that in themselves it is impossible to differentiate between symptoms due to dynamic and to static change, an extensor response which is present for five minutes, a knee-jerk which is absent for the same time, are indistinguishable from those that endure.

Defects of the Clinico-anatomical Method

When we endeavour to link the clinical symptoms of illness with any tissue modifications found subsequently, our path is beset with pitfalls of a sufficiently obvious kind.

1. In the first place, we have to consider the precise nature of the semeiological picture during life. Adopting Jacksonian terminology, we must state whether the symptoms are "positive" or "negative"—that is, whether they correspond to enhanced or diminished function, to its presence or absence. Clearly, excitation of function cannot be associated with destructive lesions, the sole direct effect of the latter must be its abolition. When we find paralyses or anaesthesias or amyotrophies, we can properly assign them to interruption or disintegration of nervous tissues. But it is far otherwise with "positive" symptoms, of which a moment's thought will convince the clinician a large part of nervous semeiology is composed. These must be produced by the action of healthy mechanisms. To attribute the involuntary flexor spasms of a case of paraplegia to lesions in the pyramidal tract is illogical, for their occurrence integrity of lower spinal reflex arcs is essential. That is to say, a prominent *symptom* is produced by the action of a *healthy* mechanism. The problem of all involuntary movements (tics, chorea, tremor, epilepsy, myoclonus, athetosis, etc.) is a problem in physiology, and will never be solved by their ascription to destroyed cell-fibre systems. Or take another example in the case of neuralgia, precisely what lesion do we expect to discover that can be correlated with it? Essentially a positive symptom, it must be caused by excitation (or release, if that is thought more accurate physiologically) of sensory mechanisms which must be in a state of health, not of depression. Can such cell-fibre systems be distinguished histologically from any others? What can we suppose is the state of the dorsal root ganglia in the persistent pains of tabes? Logic insists that a neurone or neurones responsible for the conveyance and experience in consciousness of impulses underlying pain must be histologically intact, and not in a condition of degeneration. To find such ganglia indistinguishable from any of the rest, so far as the cells are concerned, would be in no way surprising, but quite the reverse.

This provides, indeed, a sufficiently plausible reason for postulating a sensory inhibiting system of *efferent* type, as has been advanced by Foerster[5] and others, both before him and since, the suggestion then would be that de-inhibition of this system by destroying agencies would allow over-action on the afferent sensory system whereby pain (for instance) would be persistently experienced in consciousness.

What changes is it rational to expect in the spinal cord of a patient who has suffered from tetanus—I mean in

relation to his clinical symptoms? Not a few modern cases are on record (cf. Aschoff and Reinhold[1]) with either minimal cellular change or indeed with none that is recognizable. So far from this situation proving disconcerting, it is, I submit, entirely the other way. The purer the action of tetanus bacilli and toxins—that is to say, the less the histological picture is complicated by antitoxin, magnesium sulphate or narcotic treatment during life—the more insignificant are the departures from cellular normality. If a patient dies from the affection we surely cannot expect to discover identical modifications in the cells whose activity has been responsible for tetanic spasm, and in those who escape paralysis has caused death. In respect of the former we should postulate, and expect to find, integrity and not disease. Logically, once more, we should be unable to correlate a pronounced symptom with any lesion of the mechanisms producing it.

2. No constant relationship holds between size of lesion and amount of functional disorder. In a given case the most prominent clinical symptoms are by no means necessarily coupled with the lesions most apparent at the *sectio*. The widespread functional disturbance of a generalized major epileptic seizure, which ranges, in fact, from hallucination to micturition, stands in no proportionate relation whatever to any "lesion" that may subsequently be demonstrated. No connexion exists between the mass of a cerebral tumour and its symptomatology, some, for that matter, are discovered only after death. For the immense range of symptoms badly classed as "subjective" no objective basis is supposed to exist—though, of course, we know they must have a physiology.

3. The localization of a symptom, a functional system, and a lesion, is in each instance a different and separate thing, and herein lies one of the more serious shortcomings of the clinico-anatomical method. A capsular haemorrhage produces a paralytic hemiplegia, but any inference that motor function is confined to the pyramidal system is clearly erroneous. Its sub tratum extends far beyond that part a lesion of which is followed by motor symptoms of a negative kind. When the contractured fingers of the hemiplegic hand open in extension as the patient warns the symptom (an involuntary movement) has nothing to do, *qua* localization, with a thrombosis in the pyramidal path. The phenomenon of micrographia doubtless is a symptom of some cases of Parkinsonism, post-encephalitic or otherwise, but it is also found in cerebral arteriopaths in hemiplegics, and in normal subjects. How, then, in the name of all that is logical, can it be "localized" in the corpus striatum, as some would maintain? The same considerations hold good in respect of the sensory system, we "refer" or "localize" sensory symptoms to or in various parts of the body, whereas, as a fact, every sensation is a presentation in consciousness, and therefore of, let us say, cortical site. Yet the lesion stands in no spatial relation thereto. Central pains arise in association with a lesion which may be situated in spinal cord, pons, *or thalamus, but whatever its position, it cannot* correspond to the place where sensation is being experienced.

Symptoms, lesions, and functional systems are not comparable, cannot be, as it were, superimposed one on the other, and obey differing rules of localization. It would be a simple matter to amplify the contention by a further series of illustrations, but one must suffice. For a number of years many writers, more especially on the Continent, have been assigning post-encephalitic ties to destructive lesions of the putamen or caudate nucleus. Now such a view can be shown to be doubly or triply erroneous, for in the first place a tic is a positive movement and must be caused by activity of motor cells, it cannot be assigned to those that are dead. Secondly, it represents a mode of activity of the motor system, and as such its intrinsic clinical characters compel us to place it at a high level in that system, certainly not at an infracortical site. Thirdly it exemplifies escape of motor funct on from control and if a lesion is to be sought therefor that lesion may be situated in transcortical inhibitory mechanisms far removed anatomically from the region whose healthy activity is causing the tic. No adequate reason perhaps exists for seeking any recognizable *lesion* for habitual movements, tricks of motor type, *mannerisms, stereotypies*, if there be any at all, it is one which is responsible for de-control only. Unfortunately we do not know what and where that may be. We postulate transcortical defect without being able to specify it.

There is, however, a still more radical objection to the mode of thinking which associates physiological symptoms with visible lesions. We must, I believe, definitely concede that in respect of the motor system (say the motor region of the cortex) excitation can produce immediately obvious motor symptoms, whereas limited destructive lesions of the same part may not cause any paralysis. Movements are represented over relatively wide areas, and unless the part destroyed is sufficiently large it may not effect any interference with movement production. Thus small lesions in cerebellum, corpus striatum or cortex itself may not be responsible for any discoverable symptom if the function or functions concerned enjoy a wide representation. To find a lesion of such a kind therefore with the active manifestation of a movement is an unsound and indefensible proceeding. I am tempted to add another corroboration of the general argument of value because it concerns a negative symptom—namely agraphia. For my present purpose the term may be taken to signify inability to write correctly as regards formation of letters and words. Say that this occurs in consequence of a stroke with right hemiplegia in a right-handed person. Assume that his incapacity is not so severe as to prevent his holding the pencil properly enough and that he has preserved in his mind the necessary ideas but—he cannot write. To ascribe this symptom to a destructive lesion which may be found post mortem in the left hemisphere is facile and the corollary is practically certain to be drawn that the area involved is a "writing centre." But surely here is a complete *non sequitur*. Have we *tried our patient's left hand?* If he can write with it there is no agraphia at all. Have we thought of trying him with his toes? It is relatively easy to write with the foot if the pencil is suitably fixed and in even more unexpected ways—for example with the pen between the teeth. I have a pen-and ink signature thus written solely by movements of the head, executed by a soldier with complete traumatic quadriplegia. Where, then, is the writing centre? At the least, it is not where a destroying lesion interferes with conduction to the right arm and hand. Did not Grock, the French clown, play the piano with his nose? And if a lesion were to obstruct the route from temporal lobe to neck muscles, would he suffer from amusia?

4. A further frequent misunderstanding in respect of clinico-anatomical correlation is concerned with the question of time. I know well, of course, that one lesion can often be shown to be older than another in the same brain, but this declaration is of minor significance compared with the inability of the neuropathologist to do more than present a static tissue picture in contrast to what has consisted in life of a physiological progression, a series of functional events. The temptation is almost irresistible to set a pronounced clinical symptom alongside an obvious structural change without considering the approximate time of development of either. If yielded to, the result may be *unfortunate*. A striking example comes to mind. The average duration of a case of rabies is only three days, its incubation occupies less than thirty, and only rarely when more than sixty—in either instance extremely brief. Some recent studies (cf. Schukri and Spatz[2]) have demonstrated conclusively that even without that short period of four days the substantia nigra is the most heavily implicated of all affected regions, many of its ganglion cells are totally disintegrated and glial scavenger cells packed full of melanotic pigment. This simple fact—namely that degeneration and disappearance of the cells of that tract are seen in acute rabic cases well inside a week—at once renders extremely suspect any ascription of the Parkinsonian syndrome of epidemic encephalitis to their absence in that affection since (apart from the definitely positive nature of the syndrome) it leaves out of account the fundamental question of the time factor. Should the objection be raised that the comparison is of two different morbid affections I may point out that in epidemic encephalitis Greenfield[3] has noted destruction of these cells by the twenty-third day. When Parkinsonism develops say two years after the acute attack, and at a *sectio* five years later outfall of the cellular

elements of the substantia nigra is apparent, how can we allege clinico-anatomical relationship if we do not know at what time they disappeared? Without such knowledge we are committing the easy error of setting in juxtaposition merely the obvious symptom and lesion and of ignoring the time component.

But there is another aspect of the same topic that merits attention. A syndrome whose unrolling involves the idea of succession in time cannot be localized by spatial rules. Discussing this point, Monakow and Mourgue[9] take as illustration a musical box, in which dissonance can be produced (1) by absence of one or more projections on the rotating brass cylinder, (2) or absence of teeth in the vibrating comb, (3) or by changing the position of the latter in relation to the former to right or left. Incidentally, we have here a useful proof of the fact that one and the same symptom can be caused by changes at different physiological levels, as already remarked. All such possibilities effect alterations in temporal succession and modify the melody, but if the question is asked, "Where is the melody localized?" it is seen to have no meaning. Its "localization" is chronogenic. Some time ago neurologists were seeing cases of post-encephalitis characterized by inversion of sleep rhythm—a rather difficult symptom to deal with, and often extremely pronounced, the youthful patients were sleepy or asleep during the day, and became imps of mischief during the night. Here is a symptom, definite and special, but where is it localized? One has only to set the question to perceive its absurdity. And this leads naturally to the cognate question of narcoleptic phenomenology. In view of the fact that all of us sleep for a number of hours during the twenty-four, what exactly do we expect to find should such a case come to necropsy? I cannot see that occasional or even frequent diurnal sleeps are calculated to effect any persisting morphological change in nerve cells, and if none is recognizable what becomes of the relation of symptoms to lesions? It is perfectly clear that the narcoleptic patient is suffering from a derangement of sleep rhythm, a hypersomnia which is merely an exaggeration of a condition recurring normally in every one of us every day, and I submit that that disorder of the processes of sleep constitutes a symptom embodying the idea of modification in time and cannot be interpreted by reference simply to static change. Even if organic lesions are seen post mortem in a case characterized by pathological sleep—as occurs often enough—it behoves the neurologist to proceed warily in his correlation of the two. To explain alterations in time processes by morphological tissue change is strictly an illogical procedure.

We have thus seen how lesions can be present without recognizable symptoms, and symptoms without recognizable lesions. So far, however, from being nonplussed thereby, I am clearly of the opinion that not only is this to be expected, but that it also throws light on the true nature of what in a superficial way is termed "disease." Rather should any scientific parlance employ the term "reaction" as explanatory of symptom-lesion relationship, and it is informative to note that some present-day psychiatrists—dissatisfied with Kraepelinian conceptions—now speak of paranoid reaction types, schizophrenic reaction types, etc., instead of paranoia, schizophrenia, and so on, once thought to constitute actual disease entities.

Interpretation of Neuropathological Change

Since no specificity, as we have found, attaches in a general way to nervous symptoms, then causation being—again speaking generally—multiplex, the homologous question of whether pathological changes can be considered specific becomes of much interest. My submission is that they cannot so be regarded, that they are nothing else than tissue reactions to noxious agents, classifiable no doubt in certain groups, they form none the less merely a series of pictures, the features of any one of which are as a fact common to numerous others.

We may begin by looking for a moment at cellular change. Now Nissl himself, who at first hoped for and believed in an unvarying correspondence between specific poisons and specific cell alterations, was compelled in the end to concede that similar or identical changes can be brought about by a whole series of etiologically distinct factors—an admission that must be fully accepted by everyone who has any knowledge of the subject. The statement of Dejerine,[10] made as long ago as 1897, that "la chromatolyse de la cellule nerveuse est une lesion banale, interessante au point de vue cytologique, mais jusqu'ici, du moins, ne repond à aucun phénomène physiologique et, partout, pathologique determine," is for practical purposes almost as true to day as it was thirty years ago. I need scarcely point out, by way of illustration, that swelling of the nerve cell occurs in fevers, alcoholism, botulism, strychnine poisoning, diffuse coloration of the achromatic substance in diphtheria, lead and phosphorus poisoning, and various mental affections, vacuolation in toxicosis from cocaine, morphine, chloroform, and in such infections as rabies, cholera, plague, enlargement of the nucleus in burns, uræmia, cholæmia, nuclear shrinkage in poisoning by arsenic, alcohol, etc., and in eclampsia, nuclear displacement in pneumonia, typhus, morphinism, cocainism, and so on and so forth. None of these reactions are mutually exclusive, none a feature of one class more than another.

Or take the mesodermal—that is, conjunctivo-vascular—reactions, considered nowadays to form the correlate of inflammation in the central nervous system. Here are included cellular infiltrates and exudates as well as glial and other hyperplasias. Assuredly there is nothing whatever specific in respect of these pathological "lesions," for they are a banal feature of the action of such totally different etiological factors as those of syphilis, tubercle, rabies, trypanosomiasis, poliomyelitis, and what not. Under the microscope it is impossible to distinguish rabies from epidemic encephalitis, the cortex of tuberculous meningo-encephalitis—so far as mesenchymal change is concerned—bears the closest resemblance to that of general paralysis. Or take the glial knots and nodules once imagined characteristic of typhus, they are found as a fact in a whole series of diverse pathological states associated with toxi-infective conditions—the very latest being yellow fever (cf. Jakob and Fralho[11]). And what of perivascular demyelination? It is seen in Schilder's encephalitis, in disseminated sclerosis, neuromyelitis optica, post-vaccinal encephalitis, some cases of measles encephalitis, and the vague "acute disseminated encephalomyelitis" that is once again arousing interest. Whether one or other of these is or is not accompanied by other reactions that may conceivably serve to differentiate is immaterial to my argument, I urge strongly that the data allow of only one conclusion—namely, that perivascular demyelination is itself nothing else than a tissue reaction common to a number of conditions which differ clinically *toto cælo*, it cannot be taken by itself, and of itself, to constitute a disease in any scientific sense. When my friend and colleague Dr. Godwin Greenfield,[12] in his latest contribution to this subject, declares that "acute disseminated encephalomyelitis is a disease *per se*, which may be brought on or directed against the nervous system by certain febrile or exanthematous diseases," I answer that he is erecting a mere tissue reaction into a disease, contrary to all the canons of nosology, and that his assumption that one *disease* can "bring on" another *disease* demands the most critical scrutiny. Only if proof were one day forthcoming of the causation of this particular histological reaction by one and the same virus, invariably, inevitably, and uniquely, could it possibly attain specific value.

But illustrations need not be multiplied. This general conception of the essential non-specificity of normal tissue reactions, whether mesenchymatous or parenchymatous, has so impressed me for a long period now by its substantial truth that I consider it unassailable. The newest corroboration comes from the distinguished neuropathologist of Munich, Professor Spielmeyer[13], I quote from his Mayo Foundation Lecture of December, 1929:

> "The same alterations are found in a lesion from trauma, intoxication from carbon monoxide, intoxication from morphine, chloroform narcosis, hypertension, pseudo uræmia, and other spasmodic conditions. Always the same alterations are seen. They are different only according to their age and intensity. When in the past they sometimes seemed to be different in

localization and there seemed to be something really typical in them further experience showed that that was an error *So these findings mean nothing in the definition and classification of disease entities* Their fundamental value rather consists in showing something common to all these diverse *structural and clinical* and so very *different* not anatomical forms of disease but similar pathogenic complexes It can be seen how the most varied injuries by a more or less long chain of causes finally lead to the same pathophysiological process (Italics mine)

These are weighty words they represent with exactness the conclusion I myself reached some time ago though applied by Spielmeyer more especially to vascular disturbances they stand for a principle capable of much wider application What the neuropathologist sees is not the response the expression of a pathophysiological process one and the same process is capable of being called into being by etiological factors differing among themselves and causing clinical symptoms also differing in their type

One or two other questions of pathological interpretation remain for brief allusion

Such expressions as "acute haemorrhagic encephalitis" "acute disseminated encephalomyelitis" "acute parenchymatous degeneration" and other analogous terms are merely descriptive *names* for pathological reactions they correspond pathologically to such clinical expressions as 'headache' or 'paraplegia" and are devoid of meaning from a nosological or etiological standpoint And it is of prime importance to note that *differing* reactions may and do sometimes occur in the *same* affection For example parenchymatous degeneration without obvious mesodermal hyperplasia characterizes some cases of epidemic encephalitis as is now fully recognized further a number of disease conditions—for example epidemic encephalitis rabies neurotubercle neurosyphilis and still others—may exhibit both types of reaction in one and the same case in different parts of the neuraxis and seemingly in complete independence of each other Attention has lately been directed by Jakob[15] Spielmeyer[16] and other workers to the occurrence in the cortex of regions of general parenchymatous necrobiosis pale or bleached in appearance often without well-delimited margin and visible only in Nissl preparation They are best seen with a low power Whether they are of vascular origin does not concern us for the moment what is significant is their identical development in morbid conditions that differ fundamentally in etiology and in clinical character and their coexistence with but separation from reactions of mesenchymal type Clearly, the inference is again justified that some of the morbid states which we have thought constituted disease entities possess no specific pathological reaction on which to base that assumption while on the other hand, a seemingly definite pathological reaction is common to a number of diverse clinical states

A final consideration bears on the question of modifications undergone by nerve cells during the normal activities of life and after dissolution has set in Histological differences between resting and actively functioning cells are sufficiently well known an extensive series of studies by Dollery[18] has demonstrated the orderly sequence whereby changes in the quantity and distribution of chromidial substance and variation in the nucleus-plasma ratio are natural results of activity and depression After activity indeed, a cell may be practically dechromatinized and yet recover its full complement of chromatin during rest The details of these changes need not delay us but their import should not be overlooked For in the examination of nervous tissues after death departures from the pattern of the resting cell do not all of necessity indicate the existence of pathological circumstances on the contrary, they may equally well be physiological and equally, therefore indicative of health and not of disease

Analogously, it becomes of cardinal importance to note that in toxic conditions as well as in "natural" conditions, changes take place in nerve cells in accordance with the period after infection at which tissues are fixed and examined This has recently been well demonstrated by Barros[19] He has injected tetanus toxin into guinea-pigs and shown by the microscope that if the tissues studied are fixed two hours after inoculation the ganglion cells of the spinal cord yield a normal Nissl picture, if after six and a half hours the cell exhibits early chromatolysis if after seventeen, it presents much more definite resemblance to the ordinary picture of a toxically degenerating cellular element Evidently a toxin may be at once dynamically interfering with cell function before histological change can be detected

The general bearing of the observation of [illegible] which some discussion has been allotted will not escape the inquiring mind They indicate the desirability and necessity of regarding 'disease processes' as resulting from vital effort to cope with noxae many strip of positive proof of health many 'lesions' are evidences of attempted repair Along such lines of thought I believe we shall gain a truer insight into the activities of the nervous system

INFLAMMATION OF THE DIAPHRAGM *

BY

ALBERT RAMSBOTTOM M.C. M.D. MANCH., F.R.C.P.

PROFESSOR OF CLINICAL MEDICINE UNIVERSITY OF MANCHESTER HONORARY PHYSICIAN MANCHESTER ROYAL INFIRMARY EXAMINER IN MEDICINE, CONJOINT BOARD OF ENGLAND

(With Special Plate)

INFLAMMATIONS in the neighbourhood of and implicating the diaphragm is fairly common but the symptoms resulting vary enormously in their severity they may be anything from a slight discomfort in the side to those suggestive of an acute abdominal condition Some of the cases which I have chosen to call chronic may exist, I think without any symptoms while some of the misleading and urgent symptoms of acute pneumonia may be the result of implication of the diaphragmatic pleura in the inflammatory process For descriptive purposes I propose to divide the subject into two parts (1) Inflammation of the upper surface or diaphragmatic pleurisy (2) Inflammation of the under surface or subdiaphragmatic abscess It must however be remembered that inflammation of the upper surface may produce symptoms resembling an acute abdominal condition and that inflammation of the under surface may on account of the distribution of the phrenic nerve produce pain about the shoulder in the supraclavicular region

It would here be convenient to remind you of the nerve supply of the diaphragm Excluding the sympathetic fibres the diaphragm receives *branches from* (1) the phrenic nerves (1) the lower six or even intercostal nerves The phrenic nerve arises from the third fourth and fifth cervical nerves but mainly from the fourth It arises from the same segment of the cord from which the supraclavicular region receives its cutaneous nerve supply thus accounting for pain being referred to the supraclavicular region—the so-called shoulder-tip pain of diaphragmatic pleurisy On reaching the diaphragm most of the phrenic nerve fibres pierce it and are distributed on its abdominal surface The phrenic nerves contain afferent

* Read before the Blackburn Medical Society April 1930

as well as efferent fibres, the former constituting about one-third They are the sole motor supply of the diaphragm in man Their sensory fibres are more limited, and are mainly distributed to the more central part, and particularly to the more central part of the abdominal surface, and the fact that the shoulder-tip pain previously referred to is the result of irritation of the branches of the phrenic is of interest, in that it indicates that the central part of the diaphragm is affected Branches from the lower intercostal nerves can be traced into the diaphragm It is doubtful if they contain any efferent fibres, but their afferent innervation is of interest Their sensory field is *the more peripheral part of the diaphragm Irritation* of this part of the diaphragm is therefore more likely to induce pain in the cutaneous distribution of the lower intercostal nerves, which embraces not only the lower costal region, but includes, of course, the anterior abdominal wall, and in that way may lead to difficulties in diagnosis

DIAPHRAGMATIC PLEURISY

In view of the wide variation of the symptoms of this condition I propose to subdivide it clinically into (*a*) acute, (*b*) subacute, and (*c*) chronic

(*a*) *Acute*

The onset is very abrupt The patient is seized with severe pain and vomiting The pain in a typical case is referred to the lower costal region, but it frequently extends to the upper abdomen and tends to radiate round the lower thorax, and, if the central part of the diaphragm be implicated pain is also complained of in the supraclavicular region of the shoulder on the same side, it does not radiate to the shoulder, but is felt there in addition to being felt in the lower costal region, in this way it can be distinguished from the pain of acute cholecystitis, which seems to pass through the side as if a red-hot stiletto had been plunged through the liver to come out at the lower end of the scapula Again, the pain in acute cholecystitis is, at its height, often referred to the epigastrium whereas, when it has subsided a little, it tends to be located over the gall-bladder It may happen however, that the initial pain is referred almost entirely to the abdomen, the patient making little or no complaint of pain in the lower costal region It is in these cases, particularly if vomiting is a conspicuous and urgent symptom, that great difficulty in diagnosis is apt to arise, and operations may be undertaken in the mistaken belief that the case is one of appendicitis, cholecystitis, or even perforative peritonitis or acute haemorrhagic pancreatitis, according to the situation of the pain, though usually in these conditions the degree of abdominal rigidity is greater than in diaphragmatic pleurisy Of all the conditions the pain is perhaps most intense in acute haemorrhagic pancreatitis There is usually moderate pyrexia, though this does not appear to be essential at the outset, as is instanced by the following case

A woman aged 41, complained of severe pain in the left lower costal and left upper abdominal regions, associated with urgent vomiting The history was that four days previously, after a supper of veal and ham pie, she went to bed feeling in her usual health In the middle of the night she woke with what she described as "terrible pain" in the left lower costal region and "could not get her breath" About 9 A.M. she began to vomit, and vomited so violently that she fainted From this time onwards she had vomited everything she had taken At first there was no pyrexia and not until two days after the onset did the temperature rise to 99·6° It then continued to rise gradually until when I saw her on the fourth day, it was 102·8°, the pulse was 112 and respirations 20 Examination revealed marked hyperaesthesia over the left costal margin and left upper abdomen, but no striking rigidity A diagnosis of diaphragmatic pleurisy was made, which apparently was correct, for the next day a friction rub made its appearance on the left side Ultimately the patient made an uninterrupted recovery

The pulse is rapid and small The breathing is impeded, but not always appreciably accelerated, and is often entirely thoracic The skin over the painful area is markedly hyperalgesic, so that touch or light pressure causes intense pain, whereas firm pressure with the hand is infinitely less painful, and may even give relief The absence of abdominal rigidity is most striking, and this, combined with hyperalgesia of the skin and the character of the breathing, is of the greatest service in differentiating from an acute abdominal condition Later the diagnosis is often put beyond doubt by the detection of a friction rub at the base or by the supervention of unmistakable signs of pneumonia

Treatment

Once the diagnosis is established, it is advisable, if the pain is very acute, to give a dose of heroin or morphine hypodermically and to apply a fomentation locally

(*b*) *Subacute Diaphragmatic Pleurisy*

In these cases the pain is not so severe It is located in the lower costal region, with or without referred pain in the supraclavicular region of the shoulder As a fairly typical example I would quote the following case, which I saw on January 9th, 1925

The patient was a schoolgirl, aged 15, with a history of having contracted a cold five days previously Three days later she complained of severe pain in the left lower costal region, which, in the course of the day, was referred to the outer side of the left shoulder but did not affect the arm The temperature was 99° She had a slight, a very slight, cough, but no expectoration The pain in the costal region was greatly intensified by breathing When I saw her the temperature was normal, the respirations were short and rather rapid—namely, 26 The chest over the lower costal margin was tender, but there was no friction sound The outer side of the left shoulder was also slightly tender, but there was no swelling and the movements at the joint were good There was no affection of any joints The next day a friction sound was heard at the base of the left lung

In some cases the pain over the shoulder is the first to make its appearance

A patient, admitted to the Manchester Royal Infirmary on June 18th, 1927, for right sided pleural effusion, gave a history that, four weeks previously, he was seized with sharp stabbing pains at the top of the right shoulder which lasted for two hours and recurred frequently until, a day or two later, pain began in the lower costal region

(*c*) *Chronic Diaphragmatic Pleurisy*

This group comprises those cases in which old adhesions exist between the visceral pleura and the diaphragm

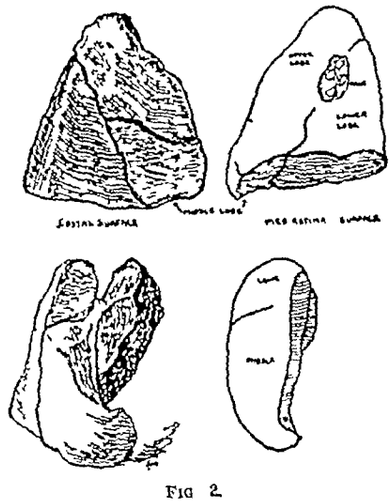

FIG 2.

Many of these cases do not appear to give rise to any symptoms In others the presence of certain symptoms may lead one to suspect the presence of adhesions, but the diagnosis can only be established when confirmed by *x*-ray examination The patient may complain of a frequently recurring sharp pain in one or other lower costal region, with occasional pain in the supraclavicular region of the shoulder, which, if present, is a great help in diagnosis Examination will reveal some impairment of movement with diminished air entry at the base of that lung There are three main types of these adhesions as revealed radiologically

Type 1—*Adhesions between the diaphragmatic surface of* the pleura and the diaphragm These adhesions may occur at any point but not uncommonly may be seen (Fig 1) in a radiogram taken laterally as pointed out by Twining[1] to extend from the diaphragmatic part of the fissure between the upper and lower lobes on the left side or between the middle and lower lobes on the right side causing tenting of the diaphragm The oblique fissures were shown by Kreuzfuchs and Schuhmaker to extend to the diaphragmatic surface of the lung (Fig 2)

Type 2—Adhesions along the periphery of the diaphragm or a the costo-phrenic angle or mediastino phrenic angle hooking up the diaphragm (Fig 3) The following case is an example

A foreman calico printer aged 41 complained of tiredne shortness of breath pain in the left side on yawning or sneezing and occasional sharp pain at the tip of the l ft shoulder The history was that four month previously he had dry pleurisy at the base of the left lung and that ever since h had run an intermittent temperature ri ng in the evening to b tween 100° and 101° with occ sional night sweat and steadily loss of weight Cough had only been very slight and accompanied by very little expectoration which had on three separate occasion been examined for tubercl bacilli with negative result Examination revealed deficient movement impaired resonance and diminished breath sounds at the left base but no adventitious sounds and no cardiac displacement X-ray examination of the chest showed the left diaphragm to be fixed and obliteration of the left costo-phrenic angle with some pl ural thickening

Type —Adhesions arising from the mediastinal surface of the lung and connecting it with either the diaphragm or as mentioned above with the pericardium (Figs 4 and 5)

The explanation of the formation of the adhesions arising from the interlobar fissures is interesting In an antero-posterior view a pleural effusion is represented in a radiogram by a more or less uniform shadow and if the effu ion is insufficient to fill the chest the shadow is seen to have a convex upper margin rising to it maximum height in the axillary line Fleischner[2] however, has shown that in a lateral view this shadow may be seen to dip into the interlobar fissures, the effusion having separated the lobe of the lung by invading the e fissures (Fig 6) In some cases this interlobar exudate di appears entirely by ab sorption in others it becomes organized, and in this way is I believe responsible for the formation of adhe ions arising from the fissures Such adhesions, we have seen may connect an interlobar fissure with the diaphragm or with the pericardium, and may, by their contraction cau e so-called 'tenting" though actually this is very slight for careful examination shows that the 'tent is composed almost entirely of adhesion

SUBDIAPHRAGMATIC ABSCESS

Any abscess in contact with the under surface of the diaphragm (except when in the liver or spleen) is spoken of as a subdiaphragmatic abscess Such an abscess may be either right-sided or *left-sided and may, in addition to* pus contain gas (Fig 7) These characteristics will, in great measure be determined by the underlying cau e of the abscess *The commonest cause of subdiaphragmatic abscess* is perforation of a peptic ulcer the resulting abscess being usually on the left side, and in view of the direct communication with a hollow viscus will contain ga in addition to pus

The perforation may be subacute or acute, for the relief of which immediate operation may have been performed Hurst and Stewart[4] in dealing with this subject, while admitting that immediate operation for gastro-duodenal perforation has enormously reduced the mortality of this complication, doubt if the frequency of subdiaphragmatic abscess has been appreciably affected, the proce s of localisation having begun before the patient is seen by *the surgeon*, or the peritoneal drainage provided being inadequate Later in the same article, when discussing the symptoms they state that "if the temperature remains raised or if after an initial fall it rises, and symptoms of a general infection occur about the fifth day after an operation for a perforated ulcer, a localized abscess is probably forming If abdominal and rectal examination show that there is no obvious local ab cess in the abdomen or pelvis a subdiaphragmatic ab cess is probably present"

When the perforation in the original peptic ulcer is very small the resulting ab-cess may not contain gas

Of the other cau e of subdiaphragmatic al cess [perforating one of the most frequent is the tracking up of an appendicular abscess The e abscesses are usually on the right side and are non-gas-containing though it may be remembered that occasionally such an ab cess may contain gas as the result of infection by putrefactive bacteria

Symptoms and Signs—The general symptom of subdiaphragmatic abscess are those of a collection of pus anywhere in the body and consist of languor loss of appetite emaciation, constipation and dry furred tongue with irregular pyrexia and rapid pulse sweating and occasional rigor The onset and sign and symptoms however, will vary with the cau e and situation of the abscess In cases following an appendicular abscess or the operation for perforation of a peptic ulcer the onset is usually insidious If five or six days after the operation pyrexia persist without any local condition to account for it, and the patient complains of pain in the lower costal region with impeded though not necessarily accelerated breathing the formation of a subdiaphragmatic ab cess should be suspected The subsequent sign will depend upon whether the abscess is situated posteriorly when the signs will be mainly thoracic or anteriorly when they will be mainly abdominal With a *posterior abscess* an area of dullness appears at the base of the lung and gradually increases in size but the upper border of the dullness being limited by the diaphragm retains the curve of the diaphragm but with an increased convexity and does not rise toward the axilla as in the case of pleural effusion Again, the apex beat is displaced upward and not laterally as in cases of pleural effusion Not uncommonly however a subdiaphragmatic abscess is complicated by the presence of pleural effusion and when this occurs the convex upper border of the diaphragm cannot be detected by percussion and the apex beat is displaced laterally as well as upwards *Over the area of dullness there is marked* tenderness which as pointed out by Hale-White is a very valuable sign Owing to compression of the lung *there may be bronchial breathing and sometimes a* result of concomitant pleurisy a friction sound may be heard If the abscess is on the right side the liver may be palpable if on the left side the normal resonance of the stomach and splenic flexure of the colon may be replaced by dullness Exploration in the tenth intercostal space in the axillary line—*the needle being pushed boldly* on through the diaphragm—may reveal pus though such a procedure is not without the risk of infecting the pleural cavity *When the abscess is situated anteriorly*, a rounded tender swelling may be felt in the upper part of the abdomen and the thoracic signs may be insignificant Such a swelling *should not be punctured* Should the abscess contain air as well as pus the signs of propneumothorax are present X-ray examination will prove of the greatest value in the diagnosis of a gas-containing abscess and reveals an air-containing space, separating the arched raised diaphragm above from the flat-topped shadow of pus below In simple or non-gas-containing abscesses x-ray examination is not so helpful for, as a rule all that can be seen is that the diaphragm is elevated fixed and immobile, while any *shadow* below the diaphragm cannot be distinguished from the liver shadow

Prognosis—In all cases of subdiaphragmatic abscess the outlook is grave, but more so in those cases *which contain* gas as well as pus.

Treatment—Surgical

I am indebted to Dr E W Twining honorary radiologist to the Manchester Royal Infirmary for much valuable assistance and for the radiograms reproduced on the Special Plate

HORSESHOE KIDNEY.

A REPORT ON TWO CASES

BY

ARTHUR JACOBS, F.R.F.P.S.GLAS.,

SURGEON TO THE OUT-PATIENT DEPARTMENT, AND UROLOGIST, GLASGOW ROYAL INFIRMARY

(*With Special Plate*)

Horseshoe kidney is one of the most frequent of renal anomalies. Statistics obtained from the post-mortem room show ratios varying from 1 in 1,580 to 1 in 500 cases. The condition results from the fusion of either upper or lower poles of the two kidneys across the middle line. The fusion, in the majority of cases, is between the lower poles, and is composed either of connective tissue or of varying proportions of renal parenchyma, which usually lies anterior to the aorta and vena cava. The ureters, as a rule, are two in number, and arise from separate pelves. They pass downwards in front of the isthmus, and it is because of their unusual position and curvatures that a horseshoe kidney is said to be especially predisposed to such conditions as hydronephrosis, renal calculi, tuberculosis, and pyonephrosis.[1] Joly[2] states that stone is at least six times more common in horseshoe kidney than in normal organs.

The mere presence of a horseshoe kidney may give rise to symptoms, but these usually depend on pathological changes in the renal substance. In the first of the two cases here detailed, although extensive changes were present on one side, the condition gave rise to no symptoms whatsoever.

CASE I.

The patient was a man of 34. His medical attendant had found albuminuria during a routine examination which had been carried out prior to treatment for haemorrhoids. There was no evidence that this was of nephritic origin, and as it failed to respond to treatment he was referred to the urological clinic at the Royal Infirmary for investigation. A healthy looking man, of medium build, he would admit to no urologic symptoms. Palpation of the abdomen revealed no tumour. *X ray examination of the* urinary tract showed a large renal calculus on the right side, occupying an unusually low level. Examination of the urine showed some red blood corpuscles and epithelial cells, with scanty polymorphs in the bladder specimen. No organisms were seen on direct smear, and no growth was obtained on culture of specimens taken separately from the bladder and kidney. A bilateral pyelogram (Fig. 1) showed anomalies typical of a horseshoe kidney, with gross pathological changes in the right segment.

Description of Pyelogram (*Fig. 1*).—The two pelves lie adjacent to the vertebral column. On the right side the shadow of the calculus can be identified, lying behind the upper end of the opaque catheter at the level of the transverse process of the fourth lumbar vertebra. Above the level of the calculus is an extensively dilated pelvis. The calyces are also markedly dilated, and their axis is median instead of lateral. The ureter leaves the pelvis at the lateral, instead of the usual median, border. The pelvis of the left kidney is of an unusual truncated shape, and some of the upper and lower calyces lie median to it. The ureteropelvic junction on this side is also at the lateral border.

Operation

In November, 1928, the right kidney was exposed through a curved lumbar extraperitoneal incision. The upper pole, which appeared to be lower than normal, was separated from adhesions by blunt dissection, and delivered through the wound. On freeing the lower pole an isthmus of renal tissue could be felt extending between it and the lower pole of the left kidney in front of the great vessels. The ureter was found in front of the isthmus, and it was divided. Working from the anterior aspect, the renal vessels, which were irregular in their distribution, were cleared, divided between clamps, and ligatured. A clamp was now applied to the isthmus as near to the middle line as the incision permitted. The isthmus was then divided, immediately to the right of the clamp, and the kidney removed. A running suture was applied over the clamp and, as the latter was withdrawn, the suture was tightened and tied. A tube was brought out through the upper angle of the wound, from the region of the cut isthmus.

The entire wound, except that part through which the tube passed, healed by first intention. During convalescence there was a continuous urinary leakage along the tract of the tube, and this, to a slight degree, is still present. The patient feels very well, his urine is clear, and he is actively engaged at his employment as an engineer. An examination of the removed kidney (Fig. 2) showed that one of the calyces had been cut across in the resected portion of the isthmus.

CASE II.

A labourer, aged 34, was referred to the urological clinic at the Royal Infirmary in December, 1929, complaining of pain in the back and haematuria. The pain was felt over the dorso-lumbar vertebrae, and had troubled him for three weeks only. It was not severe, but became aggravated after about an hour's work, which at that time consisted in stoking a furnace. He stated that during the first week following the onset of his pain the urine had been intermittently red, but that for the past two weeks it had been quite clear. Chemical examination of the urine showed a trace of albumin, but was negative for blood. Palpation of the abdomen revealed no abnormality, and pressure in the lumbo-costal angle on both sides did not elicit any tenderness. Plain *x* ray examination of the urinary tract was negative. A bilateral pyelogram (*Fig. 3*) showed the anomalies associated with a horseshoe kidney, with a hydronephrosis in the left segment.

Description of Pyelogram (*Fig. 3*).—The left renal pelvis and middle calyces are extensively dilated. All the calyces, except the upper group, are directed medialwards. The ureter leaves the pelvis at about the mid-point of its lower rounded border. The right pelvis lies almost in contact with the transverse processes of the third and fourth lumbar vertebrae, and the ureteo-calicine angle is diminished. The axis of the calyces is in the normal lateral direction, and the ureteo-pelvic junction occupies the normal median position.

The hydronephrosis present was not considered sufficiently severe to demand surgical intervention. The patient reported recently for re-examination, when he still complained of suffering from back pains. He does not appear to be handicapped in any way, however, as a result.

For the carrying out of any successful surgical procedure on a horseshoe kidney a previous recognition of the existence of the renal anomaly is of distinct aid to the surgeon. The condition can seldom be recognized by abdominal palpation and Rovsing's sign, the causation of a characteristic pain by increasing the curvature of the lumbar spine or making the muscles of the back tense, which is relieved when the patient lies down, is not of much diagnostic value. The shadow obtained by the plain *x* ray examination of a fused kidney is usually too indefinite to admit of an accurate interpretation. Pyelography is generally the only method whereby fusion can be recognized. The abnormalities present in a pyelogram of a horseshoe kidney are due to failure of rotation of the renal pelvis.[3] In consequence the axis of the calyces is median or anterior instead of lateral, and the ureter leaves the pelvis from its lateral or anterior aspect.

Access to a horseshoe kidney is best obtained by the retroperitoneal route. The anterior transperitoneal route, as suggested by Rovsing, gives a good exposure of the isthmus, which is the most difficult part to deal with. A grave disadvantage of this approach, however, is the exposure of the peritoneum to infection. This is obviated by the postero-lateral incision, the anterior limb of the incision being carried further forward than usual. This gives an adequate exposure and working field. In dealing with the isthmus the division should preferably be made in a wedge-shaped manner, so that the cut surfaces can be approximated. A urinary fistula should be a rare sequel to the division of the isthmus, for the calyces are generally confined to the upper and middle portion of the renal mass. The lower calyx, however, extended into the isthmus in the patient operated on by me (Case I), and was therefore cut across in the course of the resection. Israel, according to Judd, Braasch, and Scholl,[4] reported a similar case, in which one of the calyces was cut across in the removal of the transverse bar.

ON BOXER'S THUMB

BY

I. H. LLOYD WILLIAMS, M.C., M.B., B.S.

HONORARY MEDICAL OFFICER HAYWARDS HEATH HOSPITAL, SUSSEX

(With Special Plate.)

SUBLUXATION of the first metacarpo-phalangeal joint is a condition occurring chiefly among boxers, with whom it has attained almost the status of a stigma of the prize ring. It does, however, occur as the result of other accidents. The deformity may be either a primary condition, as with boxers, or a residual condition arising from a complete dislocation. In boxing the subluxation is produced by a blow on the distal portion of the thumb when it is not efficiently supported by the clenched fingers. The impact of a properly delivered blow should in no case directly affect the thumb, but it may be damaged by the opponent's guard.

Anatomy

The head of the first metacarpal is somewhat flatter than the head of the other metacarpals, and strong lateral *ligaments bind it to the phalanx. Crossing the palmar aspect of the joint in question are the tendons of the* adductor obliquus, opponens, and flexor brevis pollicis muscles. The first two are inserted by a common tendon into the ulnar side of the phalanx, and the short flexor into the radial side. In each tendon is a sesamoid bone provided with a separate synovial membrane for its articulation with the metacarpal. Below the sesamoids the tendons are fused together by fibro-cartilaginous tissue which is intimately attached to the anterior ligament and capsule of the joint. The capsule, which is lax in the flexed position, is drawn down during flexion and is thus prevented from being caught between the bones. Situated dorsally are the extensors and a weak ligament.

Movements

The *active* movements of the joint are flexion and extension. The *passive* movements are (1) a lateral hinge movement corresponding to adduction and abduction of the other digits, (2) a gliding movement in the horizontal plane, the base of the phalanx being displaced towards the palm of the hand. A similar gliding movement of phalanx on metacarpal can be produced in the fingers, but it is of less extent. With very long lax ligaments hyperextension and some degree of subluxation may take place normally as a result of active movements without apparent injury to the joint.

The accompanying skiagrams may be considered typical of (*a*) the normal, and (*b*) the subluxation in boxer's thumb. The subject of this particular joint had had a complete dorsal dislocation, and subluxation resulted. Note particularly a dislocation of the phalanx in the horizontal plane towards the palm and the wide gap between the sesamoids and the head of the metacarpal.

Symptoms

Immediately after the injury the patient complains of pain in the joint and of weakness, particularly as regards grip. There is not usually much swelling at the time. If left untreated, weakness continues and is accompanied by limitation of movement, both active and passive. In old-established cases the joint is almost immobile. It assumes a position of semiflexion, and becomes somewhat fusiform in shape from thickening of the capsular structures. The swelling tends to be more abrupt than in rheumatoid arthritis.

Treatment

Digital reposition of the bones is easily accomplished by manipulation in the horizontal plane, with or without traction in the long axis of the thumb. A correct position is, however, not generally maintained. The problem therefore, is not so much to reduce a dislocation as to make this reduction permanently effective.

Dislocation does not occur unless both the lateral ligaments and the capsule of the joint have been ruptured. The posterior ligament is relatively inefficient compared with the lateral and anterior ligaments. I have confirmed this by numerous experiments on the cadaver. A complete dislocation, in which the joint capsule and ligaments are ruptured, involves also a tearing of the attachments of the sesamoids to the metacarpal head. But in no case was there intervention of fibro-cartilaginous or other tissue between the articular surfaces or between the tendons and the metacarpal although I had imagined at one time that such intervention was a possible cause of failure in maintaining reduction.

Recurring or persisting deformity is caused by the unopposed traction of the short muscles of the thumb in the presence of rupture of the lateral ligaments and capsule. Treatment must therefore be directed to neutralizing this muscular pull. The first essential is a dorsal reduction of the lower end of the phalanx whereby it is brought into correct anatomical alignment, while maintaining a certain degree of flexion of the joint. This semiflexed position is best maintained by a special splint which exerts backward

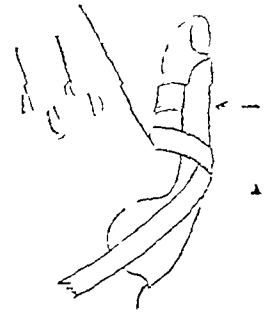

FIG. 3.—Illustration of the splint.

pressure on the lower end of the phalanx and the tension and counter-pressure both on the distal end of the phalanx and on the metacarpal. The moulded metal splint illustrated was made for me by Messrs. Lindsey and Son of Brighton. It should be worn for about fourteen days to allow the healing of the capsule and ligaments. Massage and passive movements should then be instituted, and the splint kept on for another week or fortnight.

Note.—I have tried both moulded poroplastic and strapping, but these methods have not proved satisfactory in my experience. Poroplastic does not lend itself to fine adjustment, and the essential counter-pressure producing a certain amount of flexion is not obtained by strapping.

OSTEITIS FIBROSA WITH INITIAL SYMPTOMS RESEMBLING RHEUMATIC INFECTION

REPORT OF CASE

BY

J. SALISBURY CRAIG, M.B., CH.B. GLAS.,

DISPENSARY PHYSICIAN, WESTERN INFIRMARY, GLASGOW

AND

JAMES H. SHEARER, M.B., CH.B. GLAS.,

STRATHAVEN

(With Special Plate.)

THE cases of generalized osteitis fibrosa described by Wilder[1], Hunter[2] and others in 1929 presented signs of progressive weakness, loss of muscle tone, anaemia, pain in the bones, and decalcification of the skeleton which were attributable to hyperfunction of a parathyroid tumour. The following case has been considered worthy of record since it conforms in many respects to these previously noted and because it was one in which an initial clinical picture suggestive of subacute rheumatism was altered by the occurrence of a pathological fracture.

In May 1929 the patient, an unmarried woman, complained of pain over the posterior aspect of the left deltoid region and the left upper arm. The regions was then examined [illegible] dyspnoea, mild pyrexia and pain

developed in June when the patient had to be confined to bed. Although the pain in the arm and chest was persistent, her general condition improved with rest, and she was eventually able to carry out her household duties to a limited extent. In August however, while stepping on to a vehicle, she experienced a sudden severe pain in the left upper arm with a sense of "something having snapped." Examination immediately after this incident revealed subcutaneous haemorrhage along the inner aspect of the left upper arm and immobility of the affected part. A fortnight later the patient was admitted to a nursing home. A hard fusiform swelling about the size of a tangerine orange was present over the lower third of the left humerus. Crepitus and undue mobility were absent. Tenderness was slight, but movements around the left elbow joint were painful and limited. Sensations were unimpaired.

Radiograms showed a *complete oblique fracture at the lower* end of the left humerus, with the fragments in fairly good position and callus formation. The hard bone in the region of the fracture was greatly rarefied. The appearances were definitely indicative of pathological fracture (see Fig. 1). This finding was supported by the history of the case in which there had been no question of external violence. Other areas of rarefaction were present in both epicondyles of the head of the radius, and in the olecranon on the left side while the right humerus, radius and ulna (see Figs. 1 and 2) and the ribs on both sides were also involved. Although the evidence pointed to the fracture having been pathological rather than traumatic in origin, healing had not been delayed since bony union was firm. The differential diagnosis between secondary carcinoma of bone and some form of rarefying osteitis then fell to be considered.

A small nodule, about the size of a *haricot* bean, was palpable in the left mamma. The patient was examined by Mr. G. T. Mowat of the Glasgow Royal Cancer Hospital who expressed the opinion that the nodule was more likely to be associated with chronic mastitis than with carcinoma. It was subsequently removed by Mr. Mowat. Histological examination revealed dense patches of fibrous tissue with very scanty adenomatous elements, indicative of chronic mastitis. It was pronounced non-malignant.

Examination of the pelvis, the chest, *and the abdomen gave no* evidence of neoplasm. Gastric analysis, after an Ewald's test breakfast, showed a normal acidity. The blood picture was that of a secondary anaemia. The urine contained a trace of albumin. Mitral stenosis was the *only other point of note* in the general survey.

The above findings, taken in conjunction with the fact that the fracture was well healed, were considered sufficient to exclude the presence of a primary carcinoma in any of the regions from which metastases to bone usually originate, and to confirm the non-malignant nature of the disease in the bones. Furthermore, the patient's nutrition was improving on ordinary diet.

The weight of evidence, then, turned in favour of some form of *rarefying osteitis*. A metabolic experiment, in which the calcium intake and output were measured over a *period* of four days, showed however that there was no excessive decalcification. The retention of calcium was slightly positive (0·3 gram CaO per day), and the calcium content of the blood was normal (0·014 per cent. CaO).

After returning home, on October 22nd, pain became more generalized and the patient was completely confined to bed. Mild pyrexia, dyspnoea, and cough with blood-stained sputum commenced in December following upon a chill. Anorexia and vomiting, not preceded by nausea and unassociated with food, supervened, oedema of the legs developed and the patient died in January, 1930, with all the signs of cardiac failure.

Although the features of the case at one stage suggested that the pathological fracture might be associated with tumour of bone, the subsequent history as well as the clinical findings indicated that it was due to a localized or arrested *osteitis fibrosa*.

ARTERIAL PRESSURE IN ITS CLINICAL ASPECTS*

BY

J. F. HALLS DALLY, M.A., M.D., M.R.C.P.,

SENIOR PHYSICIAN TO MOUNT VERNON HOSPITAL AND TO THE ST. MARYLEBONE GENERAL DISPENSARY

In 1628, close upon 302 years ago, William Harvey published his observations on the circulation of the blood. The fundamental characters of his immortal discovery are *still acknowledged* to be in the main identical with those that he portrayed, without which no study of blood pressure would have been possible.

Meaning of Blood Pressure.—A certain level of blood pressure is essential for every individual in order that the circulation may be maintained. It is only when this level is too high or too low that symptoms are apt to arise. In physics blood pressure may be defined as that pressure exerted by the blood at a given instant upon a given point in the circulatory system. In physiology the term includes not only arterial, *capillary, and venous pressures*, but also *the pressure of* the blood upon the interior of the heart itself. In everyday language, however, the term is employed solely to designate arterial pressure. In its clinical aspects arterial pressure represents "a force originated by the contractions of the heart, maintained by the reaction to distension of the arterial walls, and regulated by the degree of resistance in the terminal portion of the arterial system" (Gallavardin).

Types of Sphygmomanometer.—Modern instruments used in the clinical estimation of arterial pressure are of two main types—mercurial and aneroid. The mercurial sphygmomanometer registers the height in millimetres of a column of mercury equivalent to the arterial pressure at the moment of investigation. The aneroid instrument possesses an expansile chamber, distension of which by increase of arterial pressure is magnified, and in turn transmitted to a fine needle travelling round a dial. Personally I find no instrument so generally satisfactory as an accurately constructed mercurial manometer of modern type, such as the Hill-Barnard-Baskett sphygmomanometer. Many practitioners prefer instruments of aneroid type owing to their smaller compass and greater portability. All aneroids, however, should be calibrated annually against a standard mercurial manometer, since after frequent use the aneroid chamber is liable to undergo over-distension and thus to give readings which are too low in high pressure cases.

CLINICAL ESTIMATION OF ARTERIAL PRESSURE

For the majority of cases the auditory method of estimation is the simplest, quickest, and most generally applicable. It is performed as follows. The patient, seated in a comfortable position, allows the bared arm to lie with the muscles relaxed upon a convenient support of such height that the armlet is approximately at the level of the heart. For patients confined to bed the instrument may be placed on a small adjoining table. The armlet should be evenly wrapped round the arm from within outward like a bandage, the tail being tucked in beneath the last fold. It should be applied as high as possible, so that the lower margin is well above the bend of the elbow, the middle of the pressure bag lying over the inner side of the arm, thus ensuring effective compression of the brachial artery. The patient's attention should be distracted by noting the rate and characters of the radial pulse. Apprehensiveness on the part of a sensitive patient should be allayed by explaining that the band round the arm will tighten for a minute or so, but that this temporary pressure is quite harmless. The pressure bag should be rapidly inflated until the pressure within it is above that *in the brachial artery*, over which *the bell of a stethoscope has been lightly placed* just above the bend of the elbow, to the inner side of the biceps tendon.

On decompression following pulse obliteration the first audible click denotes the level of the systolic pressure. As the external pressure in the bag is permitted gently and evenly to fall a variable murmur phase becomes audible, passing into a longer sequence of *sonorous* thuds, which gradually reach a climax of intensity before being succeeded by a series of dull and muffled sounds, the fourth auditory phase, preceding silence. The first dull sound following the last loud thud denotes the level of the diastolic pressure. By subtracting the diastolic pressure from the systolic one obtains the differential (so-called pulse) pressure. These figures, along with the pulse rate and characters, can readily be entered in the case notes, and constitute "the complete arterial pressure picture."

*An address given to the Kensington Division of the British Medical Association on March 19th, 1930.

Importance of the Diastolic Pressure.—Of the two ends of the pressure scale the diastolic is by far the more important in that it is a measure of the burden which the arterial walls and aortic valves must continually bear while the systolic represents only an intermittent and superadded load. Further, the diastolic pressure constitutes a valuable measure both of peripheral resistance and of eliminatory capacity. The differential (pulse) pressure, obtained by subtracting the diastolic from the systolic, represents the cardiac load and is almost a constant in health between the age of 20 and 50.

Physiological Factors in Arterial Pressure

Numerous physiological factors cause considerable fluctuations in systolic arterial pressure, the diastolic being much less influenced. The chief factors that bring about increase in pressure are body weight and, to a less extent, height, psychical stimuli, restless sleep and nightmares, food and alcohol, the rise being soon succeeded by a fall, tobacco in those unaccustomed to its use, muscular work, mental exertion, puberty, and the menopause. The factors which cause a fall are rest and quiet sleep, fatigue and fasting, menstruation and pregnancy cause variable effects.

Menstruation.—During the week preceding menstruation both pressures rise. With the onset of flow they fall rapidly, to reach their lowest levels at the end of the period; during the next fortnight of the intermenstrual cycle arterial pressures gradually return to the previous standard levels.

Pregnancy.—As yet there is no absolute agreement as to the levels of arterial pressure in pregnancy. Most of the figures given in the literature are too high. In primiparæ below 30 years of age one does not, as a rule, expect to find a systolic pressure greater than 95 to 115 mm. of mercury, nor a diastolic respectively greater than 50 to 75. In multiparæ the pressure tends to range slightly higher, being probably influenced by age. During the latter end of pregnancy there may be a gradual and slight rise. Nevertheless 60 per cent. of all cases are below a maximum of 125 mm. Another 25 per cent. with systolic pressures varying between 125 and 140 may be regarded as potentially toxic, and require more careful watching than is usually given. The remaining 15 per cent. with systolic pressure above 140 and diastolic correspondingly elevated may be regarded for the most part as definitely toxic. In such cases albuminuria and occasional casts are frequently met with. If the pressure still goes on rising the patient's life becomes endangered and premature termination of pregnancy may be necessitated.

Climacteric.—About the climacteric epoch a benign form of hyperpiesia may occur, most frequently in multiparæ inclined to obesity and constipation, the condition being aggravated by worry and anxiety. Faulty endocrine balance in the directions of ovarian insufficiency and adrenal hyperactivity almost certainly plays a large part in causation.

Clinical Investigation

Supposing one has in the consulting room a patient in whom some abnormality of arterial pressure is suspected, what is the best procedure to adopt? On accurate diagnosis correct prognosis and control alike depend. Hence it is well to begin with a detailed inquiry into the personal and family history. Systematic investigation of the cardio-vascular system follows, first estimating arterial pressure and pulse rate, and then noting the condition of the superficial arteries, the position and character of the apex beat, the size of the heart and of the great vessels at its base by careful percussion, together with the quality of the cardiac sounds. Inspection for the possible presence of oedema, examination of the fundi with the ophthalmoscope, and urinary and blood tests complete the special investigation.

Symptoms of High and Low Arterial Pressure

Uncomplicated high arterial pressure is usually unaccompanied by symptoms. Only in later stages in the presence of associated conditions does the patient begin to complain. Even arterio-sclerosis is not a necessary concomitant of high pressure; for about half the total number of cases exhibit standard or even low pressure. In the absence of conditions of association the subject even of a high grade of pressure may feel quite well. Indeed a dramatic feature of hyperpiesis, to which I have drawn attention, is the feeling of comfort and well-being on the part of those about to succumb to cerebral haemorrhage. If a patient with a perilously high pressure expresses himself as feeling particularly fit, then is the time to beware of sudden and desperate events. Subjective sensations may be met with in the course of high pressure in the following order of frequency: fullness, heaviness, pressure feeling, or throbbing in the head, often aggravated by mental effort, dizziness on exertion, palpitation or precordial pain amounting at times to angina, dyspnœa on exertion, drowsiness and disinclination for effort, impaired memory and concentration, irritability, insomnia, anxiety states, gradual failure of vision or sudden one-sided blindness, neuralgia, migraine, epistaxis, uræmic symptoms.

One striking fact, which I emphasized last year, is that the majority of these symptoms are identical with those found in cases of low arterial pressure, but arise from opposite circulatory causes of excess on the one hand and defect on the other.[2] Dizziness in hyperpiesis results from cerebral congestion; in the low pressure case it is postural and readily induced by sudden change from recumbency to the vertical position. Again the feeling of well-being may precede cardiac failure. A notable example is afforded in the death on March 16th, of General Primo de Rivera, the ex-Dictator of Spain. As reported in the daily press at 9 a.m. his two daughters and his son saw him sitting up in bed dealing with his correspondence. He told them that he had had a good night's rest and had never felt so well. One hour later he died of cardiac failure consequent upon influenza.

The high pressure individual is often the subject of excess metabolism and labours under the strain of acid retention with inability adequately to eliminate waste products, the low pressure individual usually suffers from faulty assimilation, the acid-base balance of the tissues being deviated to the alkaline side, and tissue destruction preponderating over repair. Now that by biochemical methods we are enabled to gain a much closer approximation to exact ideas as to how errors of metabolism may be corrected and faulty balance redressed, we can formulate measures of control with far greater certainty. It is only from a broad biological standpoint which takes cognizance of early departures from that delicate adjustment of vital functions that we term "health" that the difficult problems of both high and low pressures can be rationalized and brought under one comprehensive law, to which I have referred both of these states as opposite expressions of failure to environment in its widest application.

Diagnosis

Differentiation of Types of High Arterial Pressure

The most direct way of attacking the problem is to regard hyperpiesis as including *all* types of raised arterial pressure, whether physiological or pathological, temporary or permanent, renal or non-renal. For the sake of simplicity one now takes out of the general group the syndrome to which the late Sir Clifford Allbutt gave the name of hyperpiesia. This malady is of considerable interest and importance in that it possesses individual features. Becoming manifest between the ages of 40 and 60, heightened arterial pressures of 160 mm. or more systolic and 100 mm. or more diastolic appear as constant phenomena in conjunction with left ventricular hypertrophy and changes in the walls of the arteries recognizable at necropsy as a diffuse hyperplastic sclerosis (G. Fran[illegible]) but distinguishable on the one hand from renal sclerosis and on the other hand from senile atheroma. From renal sclerosis hyperpiesia is differentiated by its occurrence in robust and often plethoric subjects who for years may experience no disability from senile atheroma, by the existence of the high pressure. Blood urea generally within normal limits, and the urine shows a trace only traces of albumin. A heart weighing 15 oz. or 20 oz. is

a common post-mortem finding. Cerebral haemorrhage or cardiac defect are the most frequent terminal events, uraemia is uncommon.

Conditions of Association

The only effective way of studying pure hyperpiesis is to watch its manifestations in early life before degenerative processes have set in. In children and adolescents, as well as in later life, there is one association that is not degenerative. This is arterial hypertonia, which is capable of inducing either a temporary angiospasm or, when true hypertrophy of arterial muscle has developed, a permanent hyperpiesis. The real degenerative changes of association are cardio-arterio-sclerosis and nephro-sclerosis.

Tests of Renal Efficiency

In hyperpiesis the situation is controlled by the state of functional efficiency of the kidneys. For those patients whose kidney function is unimpaired one can do much, for those in whom the renal secreting substance is already gravely damaged one can do little.

Blood Tests.—The term "nephritis" in connexion with raised arterial pressure is universally taken to mean interstitial or toxaemic nephritis (chronic Bright's disease), and the order in which the non-protein constituents of the blood are affected is as follow. In the earliest stages there may be a rise of the blood uric acid above the normal 4 mg. per cent. without the other fractions being affected. The blood urea nitrogen, which in private patients does not exceed 15 mg., and in hospital patients 20 mg. per cent., is next acted upon and may rise well above 100 mg. per cent. It is, however, accepted that a figure for blood urea nitrogen of above 100 mg. per cent. persisting over a lengthy period of time denotes a prognosis of almost certain fatality within twelve months. Creatinine nitrogen is the last to be affected, as it is so easily eliminated, its normal figure is 1 to 2 mg. per cent., and a rise of over 3·5 mg. per cent. almost invariably indicates a hopeless prognosis. With regard to the alkaline reserve, this as a rule is only affected during late stages. The most common cause for a notable diminution of the CO_2 combining power of plasma (normally not below 55 c.cm. per cent.) in nephritis is an inability on the part of the kidney to excrete acid phosphates, with a consequent rise in the blood phosphorus figure (the normal inorganic phosphorus in the plasma is 4 mg. per cent.). This interferes with the buffering power of the blood, and the alkaline reserve may fall to 30 c.cm. per cent., or even lower.

Urine Tests.—Where blood examination is difficult or impracticable, MacLean's urea concentration test can be performed. It involves the taking of 15 grams of urea in 100 c.cm. of water, and the analysis of specimens passed at half-hourly intervals for urea, the concentration of which should be well above 2 grams per cent., which indicates that the kidney efficiency is uninjured.

ETIOLOGY

Hyperpiesis is probably due to a variety of causes. Hereditary and familial influences undoubtedly play a part as also do protective and mechanical factors. Many cases arise as the result of long-continued anxiety states, or of emotional shocks, which through endocrine-sympathetic influences send up arterial pressure and induce angiospasm. This hypertonia of the vessel walls, at first transitory, may pass into a state of permanent contraction, and finally end in true thickening of the muscular coats. In many cases a still further explanation is required, which in my judgement is often afforded by toxaemia, either induced by bacterial toxins or by intoxications of endogenous or exogenous nature. It is probable that such toxaemias do not become operative in raising arterial pressure unless some basic disturbance of metabolism is present.

PROGNOSIS

Uncomplicated hyperpiesis is much more amenable to control than when associated conditions of degeneration, especially of the kidney, have supervened. Endocrine-sympathetic cases, inducing angiospasm in high pressure states and hypotonia in low pressure states, can often be favourably influenced. In pressures of moderate grade a fair prognosis may be given, as at the menopause, especially in patients with endogenous obesity. Cardio-vascular defects demand a more guarded opinion. In cases of *permanently raised pressure the onset of commencing heart failure* is of the gravest import. The signs of this are a drop in pressure with dyspnoea, cyanosis, premature contractions either single or grouped, gallop rhythm, *total arrhythmia, and continuous acceleration* of the pulse rate. Any combination of these signs points to cardiac defect. A diastolic pressure continuously of 120 mm. or more frequently indicates renal involvement, and if maintained at 135 mm. or higher implies a grave outlook.

CONTROL

I prefer to speak of control rather than of treatment, since it is not in every case that treatment is required. To attempt by indiscriminate use of vaso-dilator drugs, such as the nitrites, immediately to lower a heightened pressure in the absence of indications of the cause is likely to be productive of considerable harm to the patient. Such harm may, indeed, be irreparable, so that it is wise to keep these powerful drugs only for emergencies. High arterial pressure resembles fever in that both are symptomatic of processes of reaction and defence against underlying disorder or disease. Unless either of these symptoms becomes so high as to threaten life, irrespective of the cause, it is illogical and futile to anticipate more than temporary reduction by a direct attack. A warning should also be given against too vigorous treatment by fasting or purgation. Each individual has an optimum pressure at which he or she feels most comfortable, often below standard levels in low pressure states, and above these levels in high pressure states, more especially when a fairly high head of pressure has to be maintained in order that the kidney may continue to secrete and excrete.

Although drastic attempts at reduction are to be deprecated, the opposite view that nothing can be done to relieve high pressures is equally erroneous. Having realized that the most potent causes of this condition are toxaemia, worry, and excess, first proceed to eliminate any that are obvious by a careful search for diseased tonsils, septic gums and teeth, infections of the gall-bladder, appendix, and prostate, and appropriate treatment directed to these and other like causes of focal sepsis. Intestinal stasis, with absorption into the circulation of toxins from this source, is a potent cause of both high and low pressures, hence directions should be given as to regular daily evacuation of the bowels to avoid straining.

Anxiety states should be dealt with by inculcating principles of self-control. For certain cases rest in bed at the outset may be necessary, for others it is inadvisable. Efforts should be directed to making environment less irksome and more harmonious. An occupation of steady routine is beneficial, and should be preferred to one of constant anxieties and sudden hazards. A sufficiency of rest should be enjoined. In general a minimum of eight hours should be spent in bed, and this time should be devoted as far as possible to quiet sleep. Enough relaxation and holidays should be taken in quiet, sunny, and congenial surroundings. Excesses and over-indulgence of all kinds should be checked.

Diet.—More people are killed by overeating than by overdrinking. Hence the pleasures of the table should be enjoyed in strict moderation. Meals should be varied in kind and balanced, with the inclusion of a sufficiency of vitamins in the form of fresh fruit, vegetables, milk, cream, and butter. Excess of fat is inadvisable, though olive oil may be taken well mixed with fresh salads. Similarly with carbohydrates, excess producing flatulence and digestive upsets, and tending to augment arterial pressure by causing obesity. Meat, including fish, should be taken only at one meal, and the quantity should be limited to the minimum metabolic needs of the body. When the kidneys are injured, a lacto-vegetarian diet becomes essential, since butcher's meat, spiced and seasoned dishes, and meat soups are harmful where there is difficulty in eliminating waste.

nitrogenous products. In general boiled meats, chicken and fish are preferable to roast joints. Eggs are usually admissible, but a light breakfast of wholemeal bread and butter, or toast and marmalade followed by fresh fruit is better than heavy dishes of fish or bacon, sausages and eggs. Table salt should be avoided when renal, cardiac, or cerebral complications are present, common pre-war table salt being substituted if craving is felt, consisting of ammonium hippurate 1 part, potassium nitrite 4 parts, potassium chloride 25 parts.

Drinks.—Water is the best and should be taken on an empty stomach an hour before meals and at bedtime. Where the water is hard, as in London, it may with advantage be softened by a permutit or other water softening plant. Pure English table waters are Stretton, Malvern, Bracebrough, and still saluatris which latter is distilled water passed over forest burnt wood charcoal to render it palatable. Of the French mineralized waters, Vichy, Vittel, and Contrexeville enjoy a deserved reputation in flushing out the kidneys. One pint of water for each five stones of body weight, imbibed during twenty-four hours, is a good working rule. Other drinks should be taken sparingly; China tea or tea freshly made with milk is to be preferred to Indian blends. H & G caffeine free coffee may replace the ordinary coffee. Alcohol is best not taken at all.

General Habits.—Tobacco is best avoided. Cigar smokers are more prone to arterio-sclerosis than pipe or cigarette smokers. Exercise should be well within the limits of fatigue, and elderly people should not vie with their juniors in tests of endurance. Motoring, but not at great speed, suits most, but not all. Golf should be preferred to tennis for those in whom age changes have begun to be manifest. Finally, the keynote of avoidance as well as of control of arterial pressure may be summed up in the four words of advice—moderation in all things.

Special Modes of Treatment

Deep breathing exercises, relaxation, and passive movements, resistance exercises, and massage have their appropriate uses. General massage combined with Swedish movements is a most useful therapeutic adjunct in lowering raised arterial pressure. X rays, high-frequency and diathermic currents in experienced hands yield good results. Some subjects benefit from ultra-violet radiation, which balances opposite abnormalities of arterial pressure. In emergencies, such as threatened or actual apoplexy, lumbar puncture is of timely aid, as well as in warding off or relieving uraemic convulsions or severe congestive headache. Venesection up to 500 c.cm., followed by fasting for a couple of days, gives relief to an embarrassed circulation, particularly in the presence of venous stasis.

Drug Therapy

For the toxaemia resulting from intestinal stasis, rectal injections every morning for three weeks of a pint of solution of potassium permanganate, 1 grain in water, after the method advocated by Dr. Nott, is often of great value, any constipation being at the same time corrected by tablets of lactobyl or taxol. Calomel at night, twice weekly in 2-grain doses, with a teaspoonful of equal parts of sodium and potassium sulphate on the morning following, *is useful in thinning the bile, and by inducing a* greater flow lessens intestinal putrefaction. Though it is impossible to disinfect the intestinal tract, monsol tablets or T.C.P. emulsion are at times serviceable in lessening toxic products of fermentation and putrefaction.

In the lesser grades of hyperpiesis 2-drachm doses of potassium chloride thrice daily in a tumblerful of water give encouraging results. For the cardiac types, theominal, a combination of luminal with theobromine, promotes diuresis and lowers arterial pressure. Iodides I have found of little use, greater effect being obtained from oral administration of the French tincture of iodine 5 minims in water or milk after meals with gradual increase of dosage, or by hypodermic injection of an iodine compound such as iodine. In all cases of *cardiac decompensation* there is no drug to compare with the time-honoured digitalis in standardized preparations.

More recent remedies are (1) liver extract, which often induces considerable lowering in the height of pressure, affords relief of symptoms in the majority of cases without arterio-sclerosis, offering the best prognosis. Hepatmone contains a histamine-like substance and is one of the best preparations for intramuscular injection up to 5 c.cm., (2) sodium sulphovanate, also where organic changes in the arteries are absent is useful in 5-grain tablet by the mouth. (3) choline derivatives, such as peronine, may be given in tablet form or acecoline (acetyl-choline hydrochloride) parenterally. (4) animasa, an extract of muscular coats of arteries of young animals, has been reported of benefit in sclerotic cases when long continued. (5) anabolin has given me no results which are appreciable.

I have left treatment by baths and waters till last, for these demand still further study. Effervescent carbonic acid baths exert on arterial pressure reduction or increase, depending upon the pre-existing state. They can be obtained either naturally aerated or artificially prepared at many spas, notably at Royat, Spa, and Nauheim. Manipulation baths and douche are beneficial in high pressure cases, and in those or low pressure associated with circulatory stasis.

CEREBRAL ABSCESS FOLLOWING TONSILLAR INFECTION

BY

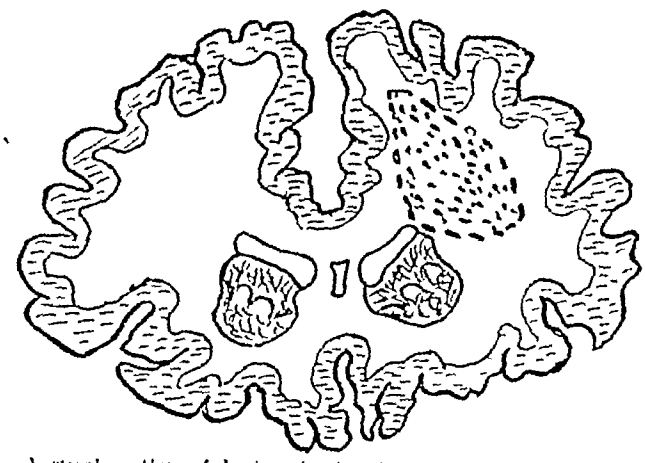
W. JOHNSON, M.D., F.R.C.P.

HONORARY PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL, AND HONORARY ASSISTANT PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

THE occurrence of cerebral abscess as a direct sequel of tonsillar infection is rare, and deserves record. In the *British Medical Journal* of June 28th, 1929 (p. 1152), Houlden describes a case of cerebral abscess following acute tonsillitis and points out that there is little or no reference to such an association in the literature.

I am indebted to Dr. Francis Roberts and to Dr. T. Pearse for some of the following notes.

A boy aged 7 years suddenly became ill one afternoon with a temperature of 101·4° and was found to be suffering from severe acute tonsillitis. In addition he had old mitral disease of rheumatic origin. He was kept in bed and his temperature fell to normal in eight days, but in view of the cardiac condition he remained in bed for a further three weeks.



Five and a half weeks from the onset of his attack of tonsillitis the tonsils and adenoids were removed. Following this his convalescence took a normal course for five days. He then suddenly developed a sharp rise in temperature accompanied by a rigor. His chest was carefully examined at this time, but no trace of broncho-pneumonia was detected. He rapidly became seriously ill; vomiting was not a marked feature. On the day following the rigor weakness was noted in the lower part of the left side of his face; on the following day some weakness in the left arm appeared, and shortly afterwards slight weakness in the left foot. On the fifth day after the rigor this had developed into a complete left-sided hemiplegia. On the seventh day he was definitely drowsy, his temperature was 101°, and the discs were reddened and congested. On this day he was admitted to hospital.

On admission the boy was in a drowsy, almost stuporous state. The temperature was 99.2°, the pulse 68, and the respirations 32. He could however be roused, and no sensory or mental aphasia was present. There was a left-sided hemiplegia, paralysis of the face and arm being more marked than that of the leg. The tendon reflexes were brisk on the right side, and were much subdued on the left. The abdominal reflexes were equal and present; the plantar reflexes were marked, extensor on the left and faint on the left. Kernig's sign was [illegible] neck seemed slightly rigid. There was no [illegible] reacted to light and to accommodation, and no oculomotor paresis. The other cranial [illegible]. Mr. Bernard Chance reported that both [illegible] red, with some swelling in their [illegible]. On examination of the heart a murmur was heard at the apex of the heart.

the lungs nothing abnormal beyond signs of some congestion at the bases could be discovered The cervical glands on the left side were enlarged

A lumbar puncture was performed The cerebro-spinal fluid showed a slight increase in globulin and total protein, the sugar reduction was diminished the chlorides were normal, and the cell count 18 per c.mm the lymphocytes and polymorphonuclears being in equal proportions No micro-organisms were seen and the culture was sterile Blood was also taken for culture, but only staphylococci which were considered to be due to a contamination were found

The gradual "march symptoms" of a hemiplegia formed a definite indication of a cerebral abscess in this case The boy's condition was extremely grave on admission and in addition he had valvular disease of the heart However, the localization of the abscess being adequate, it was decided that the chance of operation should be given, but unfortunately he did not survive

Vertical section of brain showing location of abscess in subcortical region of right frontal lobe

A post-mortem examination was performed by Dr R T Chadwick, who reported as follows

The brain dura mater was dark in colour and congested The arachnoid and pia mater were intensely congested and opaque, the blood in the vessels was fluid No signs of emboli and no pus were discovered The convolutions on the right side were flattened and the ventricles were filled with clear cerebro-spinal fluid, the left being normal in size, the right flattened by the abscess

The abscess, which was filled with greenish red thick pneumococcal pus, was 2½ inches in diameter and circular in shape, it was situated posteriorly to the fissure of Rolando, extending downwards from the vertex about 1½ inches on the external surface and the same distance on the internal surface of the right hemisphere lying about 1/8 inch deep to the brain surface On the vertex the meninges were intensely congested and the abscess showed signs of pointing The medulla was congested, and there were no pressure marks No sign of tuberculosis or post basic meningitis was detected, but the brain substance was intensely congested generally

The tonsillar fossæ were found to be healing after the operation, and no sloughs were present The cervical glands were slightly enlarged, but there were no abscesses therein The lungs showed an early and moderately intense broncho-pneumonia, the air passages were intensely inflamed There was great right sided dilatation of the heart the mitral orifice admitting two fingers Old endocarditis was present on the mitral cusps, but the tricuspid and aortic valves were healthy There was general congestion of the alimentary system, and the mesenteric glands showed evidence of past healed tuberculosis The kidneys were greatly congested

There are two theories of the production of cerebral abscess after tonsillectomy One is that infected pulmonary emboli result from the sepsis in the tonsillar bed, the other, that septic material is inhaled while the patient is under the anæsthetic, and that the cerebral abscess is secondary to one or other of these conditions The present case—in which early broncho-pneumonia was demonstrated at the necropsy—would appear to fall into the group of the latter theory The possibility of cerebral abscess, though rarely associated with tonsillar infection, is not to be ignored

ORBITAL CELLULITIS IN CHILDREN.*

BY

E TEMPLE SMITH, F R C S Ed, D O Oxon, F C S A,

HONORARY OPHTHALMIC SURGEON TO THE ROYAL ALEXANDRA HOSPITAL FOR CHILDREN AND THE ROYAL NORTH SHORE HOSPITAL, SYDNEY, AUSTRALIA

SINCE orbital cellulitis may occur in children of a few weeks old there is no age limit The essential feature is proptosis of the eye associated with signs of inflammation Proptosis alone is not sufficient for its diagnosis Proptosis unassociated with inflammation may be caused by a cyst, a mucocele, a new growth, or what not Until one meets the combination of a congested eye and pink swollen lids with proptosis the diagnosis cannot be established Once made, a grave prognosis should be given and the help of the specialist sought

The diagnosis is not, however, always easy, as it is at times very difficult to be sure whether or not proptosis is present when chemosis of the conjunctiva and a swollen lid are the most prominent features But it is on the existence of this sign that the diagnosis will depend Proptosis is mechanically produced by congestion of, or exudation into, the orbital tissues behind the orbital fascia This is a dense and well-fitting septum separating the orbit proper from the conjunctival sac and the anterior segment and interior of the eyeball It matters not how severely infected an eye may be, orbital cellulitis, with its cardinal symptom of proptosis, will not arise unless the orbital fascia is penetrated

It is clear, then, that orbital cellulitis must not be diagnosed because oedema of the eyelid is present, or even cellulitis of the eyelid The latter is often due to the spread of infection from a hordeolum or impetiginous sore in the neighbourhood, and oedema can often be traced to a cellulitis of the scalp or face, or dacryocystitis, and is then present merely by extension, owing to the loose cellular structure of the lids

Again an intense purulent conjunctivitis, gonorrhœal or diphtheritic, may occasionally give rise to a pink and swollen lid, ocular diphtheria is frequently at first monocular The diagnosis will be established by the presence of a profuse discharge or of a membrane on the everted lids For the determination of the presence or absence of proptosis lid retractors are essential These may be improvised by the use of two hairpins bent over near the blunt end If a local cause has been discovered for the swollen lid, whether abscess, conjunctivitis, dacryocystitis, or foreign body, it will be treated on appropriate lines If none such is found and proptosis is present or strongly suspected, a grave view must be taken of the case, as it is one of orbital cellulitis

Orbital cellulitis in children has, so far as my experience goes, three chief causes

1 Skin infections, such as impetigo, hordeolum, fly-bite, boils, or any facial wound, with accidentally superadded virulent infection This is more likely to be met with in older children The temperature is generally very high, septic cavernous sinus thrombosis and general septicæmia with pneumonia are likely to supervene and they often end fatally and rapidly The infection passes by the angular vein to the cavernous sinus Fortunately such cases are rare

2 Nasal sinus infection, the commonest cause is met with in young infants as well as in older children The temperature is not usually very high and the child is not very ill The eye is pushed outwards as well as forwards This is a strong diagnostic point I will go so far as to say that if the eye is not displaced outwards the case is not nasal in origin In these cases the services of the rhinologist should be sought, he will, if he thinks necessary, open up the antrum or ethmoidal cells I believe the most usual condition is an ethmoiditis If the proptosis is only due to oedema it will gradually subside If, however, pus has formed in the orbit a counter-opening between the nose and eye may be needed Convalescence is slow but sure, and the eye is not usually in jeopardy I have seen a considerable number of cases of this type of cellulitis in the last fifteen years They are sometimes associated with the exanthemata

3 Osteomyelitis or periostitis of the orbit is a third principal cause Until about three years ago I had not seen such a case I was then asked to attend a young

*An address given to the Paediatric Section of the New South Wales Branch of the British Medical Association on April 11th 1930

infant with a high temperature and pink oedema of the eyelids of both eyes who was very ill There was no injection of the ocular conjunctiva As both eyes were affected it was difficult to say whether or not proptosis was present I believed, however, that it would be by the morrow, and that it was an early case of septic cavernous sinus thrombosis, that nothing could be done but that my rhinologist colleague should be asked to be concurred He did concur On the next day I still found no ocular injection to speak of and no definite proptosis although the lids were more pink and swollen I realized then that I had made an erroneous diagnosis, being deceived by the binocular affection which will generally point to a common origin I asked that my colleague should see the child again He found an osteomyelitis of the lower rims of both orbits Incisions were made over the malar bones and the child recovered This was not a typical case however, as it was binocular—surely a rare occurrence Furthermore although there was osteomyelitis of the malar bones, the lesion was anterior to the attachment of the orbital fascia, therefore though oedema of the lids was present, there was no orbital cellulitis

I have since seen three cases of orbital cellulitis (monocular) caused by osteomyelitis of the orbit and not apparently, associated with or due to sinus infection I am sure that these cases are metastatic They have not been coincidental with a similar lesion in the long bones and epiphyses although they are without doubt analogous The child becomes very ill indeed with a high and septic temperature Pink oedema of the lids and definite proptosis are early signs The eye is pushed forward without being pushed outwards Presumably the eye might be pushed to some extent away from the side of origin of the infection, wherever it might be, but in the early stages at any rate, when the proptosis is merely due to oedema and not to formation of pus, there is no lateral displacement This is in contradistinction to those of nasal origin In the last three cases I have seen the point of maximal swelling and tenseness of tissues has been at the lower outer side of the orbit Possibly a trauma may have been the exciting cause

In the first case I was not called in for several days as a tentative diagnosis of a nasal origin had been made and the rhinologist had explored the sinuses with an indecisive result and with no improvement in the patient I found the outer lower orbital margin tense and swollen and incised it here getting pus freely The boy had a high temperature for many weeks and was very ill Although there was free evacuation of pus the orbital oedema and proptosis persisted and in spite of all efforts the cornea sloughed and the eye had to be eviscerated Subsequently he developed a mild osteomyelitis of the facial surface of the malar bone

The next case was that of an infant seen in private with proptosis and similar symptoms I temporized for a day and then opened the orbit at the outer angle evacuating pus Again the orbital oedema was so great and persistent that the cornea sloughed and the eye had to be eviscerated though the child recovered Sequestra formed for a long time

The third case was that of a boy of 5 with the same symptoms of high temperature severe illness inflammatory central proptosis and the chief swelling at the lower outer orbital margin He had been ill two or three days This time profiting by my experience I opened the orbit within half an hour of seeing him and passed a sinus forceps through the orbital fascia down to the bony floor and rim No pus was seen but on the next day it appeared alongside the tube which had been left in The wound was kept open the proptosis went steadily down and the eye was never in danger He had a septic temperature for several weeks and had some meningeal symptoms which however subsided on lumbar puncture *Staphylococcus aureus* was found in the blood and urine so that there was evidently a very generalized infection Later he had an attack of osteomyelitis of the tibia

To recapitulate apart from cases of orbital cellulitis due to facial infection, in which the orbital condition is only an incident in a fatal septicaemia, there are two main causes The first, and the most common, is nasal sinus infection, with outward displacement of the proptosed eye and not very severe general illness Here the rhinologist can give most help, and if he is called in early incision into the orbit will probably be avoided The second is metastatic osteomyelitis or periostitis of the orbital walls, with severe illness and temperature and central proptosis The lesson I have learned from these latter cases is that early incision (as in the analogous disease of the long bones and epiphyses) is essential if the eye is to be saved When once the orbital tissues are thoroughly infiltrated and oedematous it seems to be difficult or impossible to bring about resolution before the cornea has sloughed owing to interference with its circulation as well as to exposure Our aim should be to prevent the phlegmonous condition by prompt incision down to the bones involved Hence the importance of early and accurate diagnosis In every case of a pink and swollen eyelid the general practitioner should realize the significance of proptosis if this exists In its absence he may temporize in his preference he should act with decision No case of inflammatory exophthalmos should be regarded lightly

Although I have dwelt in more detail on the important symptoms of the type of orbital cellulitis due to bone infection by the blood stream that is not because it is the commoner but because it is the graver and demands the most prompt rule in its treatment According to Poeschmore than 60 per cent of cases are due to nasal infection He is referring to adults and I think that this applies much more so to children owing to the thinness of the orbital walls In my own practice orbital cellulitis in adults is exceedingly rare whereas in children it is at least not uncommon

My aim in this short paper is twofold (1) to emphasize the importance of proptosis when associated with inflammation (2) to attempt to make clear the difference in signs and symptoms of the two main types of orbital cellulitis and the difference in outlook and treatment which each demand

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

RENAL CYST CONTAINING CALCULI

(With Special Plate)

THE following particulars of a renal case upon which I recently operated will, I think be of general interest

A man aged 62 had always had good health until many years *ago* when he noticed a swelling in his left lower abdomen He consulted a surgeon who after examination advised an operation After the operation he was told that there had apparently been a cystic condition of his left kidney the wall of which had been removed and a drain put down into the cavity He made a good recovery and had no trouble until three years ago when the swelling returned on this occasion his doctor aspirated and drew off a large quantity of fluid

A few months ago he came into my hands and I found a large mass occupying a considerable proportion of the left hypochondriac and lumbar regions of the abdomen. It was dull on percussion and its range of movement was practically nil. Examination showed a corn-cob like mass of calculi (see plate

A cystoscopy having been performed and a pyelogram taken the efficiency of the right kidney was proved good No obstruction could be made to travel more than an inch up the left ureter but on the right side there was a normally placed organ I was then decided to explore him

Operation—The old scar on the anterior abdominal wall was removed and the abdomen was opened as carefully as possible The sac of the cyst was however so adherent to the abdominal wall that it was at first punctured and a dark grumous looking fluid escaped. This being controlled the cyst was slowly separated from adhesions with which it was completely surrounded It was no easy matter since it was necessary to avoid as much as possible damaging the numerous vessels of the mesentery which ran across it Ultimately however the whole cyst was freed and taken out With the exception of the descending colon bowel was not seen throughout the whole operation we had been apparently working in a retroperitoneal position from the start enlarging kidney having pushed everything in front of it anteriorly The cavity was drained and the aperture in the mesentery closed. The patient made an uneventful recovery

Pathology—On the sac being opened a dark grumous fluid escaped The sac was found to be composed of enormously dilated kidney pelvis and calyces with numerous deep calyces The kidney proper was represented by a thin

of bright smooth, copper-coloured calculi, which on examination proved to be composed of pure triple calcium phosphate The kidney substance itself was practically non existent, being stretched in a thin layer round the surface at the back of the sac The left ureter was tightly stretched over the wall of the sac, there were no stones in it

I am indebted to my colleagues on the honorary surgical staff of the General Hospital Darlington—Mr Pridham for an excellent pyelogram, and Mr Pearson for assisting at the operation

DAVID R E ROBERTS, M B, M Ch,
Honorary Assistant Surgeon Darlington General Hospital

TRAUMATIC RUPTURE OF THE SPLEEN

A case of traumatic rupture of the spleen in a girl aged 9 is perhaps sufficiently unusual to be of general interest particularly since the patient eventually recovered after delayed splenectomy

The patient, while crossing a railway line, fell on a rail hitting her abdomen with such force that she was unable to move She was lifted up and carried home where she was seen by Dr Daniel, who sent her into hospital with the provisional diagnosis of a ruptured viscus She vomited immediately on admission, and three times subsequently but there was no blood in the vomit nor was there any haematuria The bowels were moved the motion being free from blood Peristalsis was heard all over the abdomen The child complained of colicky pain but could not localize it The abdomen moved freely and there was no rigidity, the hepatic and splenic areas were examined, but no evidence of rupture could be found nor was there any sign of a collection of fluid in the abdomen The pulse was below 100, and the temperature was normal She was kept under observation for two days, when a temperature of 100° developed, and she complained of pain and tenderness on pressure over the appendix area

The abdomen was opened through the right rectus Free blood was found in the peritoneal cavity, especially in the left hypochondriac region, this was swabbed out, and a ruptured spleen became evident The pedicle was clamped and the spleen excised Recovery was uneventful except that two weeks after the operation the patient developed scarlet fever

A blood count, seven days after the operation, was as follows red cells 4,200,000 per c.mm., white cells 9,700, haemoglobin 75 per cent., colour index 0 9 The differential count was polymorphonuclear neutrophil leucocytes 52 per cent., eosinophil cells 1 per cent., basophil cells 0 5 per cent., lymphocytes 43 per cent., and large lymphocytes 3 5 per cent There was no anisocytosis nor poikilocytosis

The girl is now in good health

CARBON MONOXIDE POISONING

AT a meeting of the Medico-Legal Society on June 26th, *Lord RIDDELL presiding*, a lecture was delivered by Professor J S HALDANE, F R S, on carbon monoxide poisoning

Professor Haldane began by remarking that it had been known for a century that CO was a dangerous poison, and that its special danger arose from the fact that it had practically no odour or warning irritant action on the air passages The first sign of any direct physiological effects of CO was observed when the haemoglobin was about 20 per cent saturated This sign was increased shortness of breath on any considerable exertion When the saturation increased to 30 per cent there was a slight increase in the pulse rate and the breathing during rest, and such action as running upstairs was followed rapidly by distinct faintness With higher saturations these symptoms became more and more marked, and with 55 per cent saturation even a very slight exertion, such as getting up from a chair, might precipitate a fainting attack Mental deterioration of various kinds was evident in the subject to other observers, though not to the subject himself If the saturation lasted any considerable time and was fairly high it was followed by headache In some persons headache occurred with 20 or 25 per cent saturation Professor Haldane proceeded to relate observations which he had made on himself in a steel chamber, and which, he said, were limited in certain respects because they could not be pushed quite up to the point of loss of consciousness When a saturation of 30 or 40 per cent was reached certain *mental symptoms began to appear, and became more and* more prominent with increasing volume One of these symptoms was impaired memory for the most recent happenings One could, for example, count the pulse but one would immediately forget at what point the counting began The pressure in the chamber where the experiments were carried out corresponded to that found at 25,000 feet above sea-level, *and he and his companion* (a Mount Everest explorer) were unacclimatized Of one hour of this experiment he had *not the slightest memory afterwards, although*, according to his companion, who was less affected than himself he was talking all the time and answering questions Until the pressure was increased his companion thought that he (Professor Haldane) was not suffering to any degree, but at length he noticed him take up a mirror to look at the colour of his lips and found that he was looking, without being aware of it, at the back of the mirror Loss of memory by itself made the conduct of men suffering from carbon monoxide poisoning quite irresponsible He had known it take as many as six men to keep back a miner from returning to his work on an underground fire where he had fallen unconscious just previously through CO poisoning In the steel chamber experiment his companion told him afterwards that during the period of his own loss of memory he (Professor Haldane) continually asked him to keep the pressure at 320 mm., although, had he been fully conscious, and realized that he was getting worse, he would not have wished to prolong the experiment The blanks of memory were often filled in with purely imaginary events Along with failure of memory went failure of co-ordination of movement The gait became like that of a drunken man, the handwriting (of which he showed examples) became progressively irregular Sensory perception of every kind seemed to be dull Thus, it frequently happened that miners, who were by no means unconscious, received bad burns from lamps which they were carrying, *but felt no pain from the burns* He had noticed himself that he tried to grasp at objects which were some distance away under the impression that they were within his reach When normal conditions were restored everything seemed to get brighter and more distinct, sounds louder and clearer The deterioration took different forms in different persons Some people simply became more and more torpid, others became hilarious, and some became extremely ill-mannered, quarrelsome, and dangerous *But whatever* the state of the person, he remained quite confident in his own judgement, just as did a drunken man It was very easy to mistake the effects of carbon monoxide poisoning for those of drunkenness

In persons who had died from carbon monoxide poisoning the haemoglobin was about 80 per cent saturated He had, however, met with one or two cases of death which must, *from the circumstances*, have been due to carbon monoxide poisoning, but in which no CO could be found in the body The victim had evidently been gassed so badly that he died from the after-effects some hours later, having been freed in the meantime from the CO by ventilation If there were 1 per cent of CO in the air breathed, 50 per cent saturation would be reached in fifteen minutes, and 80 per cent, causing death, in twenty-three minutes If, however, the victim were exerting himself while absorbing the first part of the CO, he might be breathing four or five times as much, and reach the 50 per cent saturation within five minutes The recognition of CO *after death* presented usually no difficulty The only condition with which it was liable to be confused was poisoning by nitrite The red colour seen after death in the lips and parts of the skin was very characteristic of CO poisoning The colour of the blood and organs when the body was opened was very definite If death had been rapid, it would be found that the blood taken from the spleen was much less highly saturated than elsewhere, and in case of very rapid death the saturation on the right side of the heart would not be very high

The most common form of death from CO poisoning was suicide as a result of inhalation of the fumes of a gas stove. The number of cases of such suicide had increased very rapidly of recent years owing apparently to the spread of knowledge of its relative ease. In Great Britain cases of accidental poisoning by gas were few and did not appear to be increasing notwithstanding the great increase in gas consumption, but in the United States they were far more frequent, probably owing to the much greater proportion of carburetted water gas used there. Carburetted water gas contained about 30 per cent. CO, whereas coal gas contained usually from 7 to 10 per cent. In many English towns, however, enough water gas was mixed with coal gas to raise the percentage to 15. On the other hand, the amount which could escape from the ordinary lighting burner was much less than was formerly the case when the old black flame burners were in general use. Apart from gas suicide, perhaps the most important cause of CO poisoning was now the gas mixture which escaped from the engines of petrol-driven motor vehicles owing to imperfect combustion. On the average this contained about 7 per cent. of carbon monoxide. Many cases of partial—occasionally fatal—poisoning occurred in garages where an engine was set going to warm up the carburettor before starting, and the precaution had not been taken of opening the door wide. A formidable problem was the *ventilation of tunnels for motor traffic*. The possibility of intoxication from CO ought always to be present to the minds of police and coroners.

In the treatment of CO poisoning the first thing was to apply artificial respiration without a moment's delay. It was probable that most of the blood had not had time to become highly saturated, and in that case recovery might be rapid. The patient must be kept at rest; exertion might cause *fainting, dilatation or paralysis of the heart*. There was a rather unfortunate popular idea that, apart from artificial respiration, the most important thing in gas poisoning was the administration of pure oxygen. When pure oxygen was given in a case of CO poisoning the pressure of oxygen in the lung alveoli would be increased six or seven times, so that CO, other things being equal, would be turned out of the blood six or seven times as fast; but in the course of the poisoning far too much CO_2 had been removed from the body. The consequence was, with oxygen, a tendency to the cessation of breathing and the slowing up of circulation, and this went far to neutralize the good effect of the oxygen itself. The best result could be obtained by a mixture of oxygen in at least 5 per cent. of CO_2. An uninformed public opinion had demanded oxygen as the best remedy, and that had militated against the use of carbon dioxide in this country. American experience, however, had shown the great advantage of adding CO_2 to oxygen. CO_2 also prevented the subsequent tendency to *pneumonia*.

Sir WILLIAM WILLCOX, after paying a tribute to Professor Haldane, and to his courage in undertaking the experiments upon himself, said that a few years ago he was on a committee which sat for nearly a year considering tests for drunkenness, and a good deal of evidence was brought forward, but he did not think a single witness told the committee what had been stated that evening—namely, that carbon monoxide poisoning might show similar phenomena to alcohol intoxication. Perhaps a not unimportant point was the percentage of carbon monoxide in tobacco smoke. He believed the percentage in tobacco might be as high as 5 per cent. As Professor Haldane had pointed out, carbon monoxide poisoning was insidious in its onset. Persons became unconscious without realizing that they were affected. He had been interested to hear him advocate a mixture of oxygen and CO_2 as a respiratory stimulant because, three or four years ago, writing a little brochure on the treatment of carbon monoxide poisoning for one of the gas companies, he had advocated the use of oxygen or air mixed with CO_2. He had also emphasized the danger of any violent moving of the person suffering from the poisoning as this might entail serious damage to the heart. It had occurred to him that it would be a useful treatment for coal gas poisoning to give a solution of hydrogen peroxide mixed with normal saline intravenously. He had used this in two cases, and both did extraordinarily well and got better, but whether this was a case of *post hoc* or *propter hoc* he could not say.

Sir BERNARD SPILSBURY, taking up the reference by Professor Haldane to the controversy as to whether carbon monoxide had any direct action upon the tissues apart from the changes in the blood, by reducing the oxygen-carrying capacity, said that it had long been known that in the more chronic forms of profound anæmia very characteristic changes occurred in the body such as an extremely fatty disease of the heart muscle and the kidneys. It was not always realized how rapidly such changes could occur in a relatively short period of anæmia if the oxygen-carrying power of the blood were lowered. He had had the opportunity of investigating cases where the hæmoglobin percentage had been considerably reduced for some time, and it only required a severe anæmia of three or four days' duration to induce these fatty degenerations. If fairly tough organs like the liver and kidney could be so affected by anæmia of that duration, certainly the brain cells must be affected, and thus the profound effects of a prolonged oxygen deprivation could be accounted for. With regard to the dangers of chronic carbon monoxide poisoning to the modern community, there could be little doubt that the exhaust gases of motor vehicles constituted a serious menace in the future. He had very little doubt that many cases of chronic CO poisoning had been overlooked in the past and present. It had occurred among workers in large garages where engines were running frequently. Unless the garages were well ventilated the possibility of CO poisoning was very present. Sir Bernard Spilsbury went on to describe a case in which a doctor friend of his, having recently moved into a new house, found that all the members of the family except himself (who was frequently away from home) were suffering from some form of illness which could not be traced to any cause. His wife and children suffered from an indefinite malaise, and one of the servants who spent most of her time in the kitchen had a return of pulmonary tuberculosis from which she had suffered many years before. The drains and other parts of the house were thoroughly examined without any cause being discovered. On going over the house at the doctor's request he found that a coke stove had been installed in the kitchen for destroying refuse, and this was kept burning day and night. It was a well-made stove with a good flue, but it had the serious defect that a metal lid, which fitted quite loosely, was lifted off when it was desired to put in fresh refuse. He suggested to the doctor that he should leave a trapped mouse on the kitchen mantelpiece. Within three days he received the dead mouse and examined the blood, in which he found a considerable amount of carbon monoxide poison. The stove was removed, and all the illness disappeared from the house from that time onwards. There was no doubt that the family had been suffering from the gases formed by the slow combustion of the coke in the stove. In estimating the fatal saturations he had never obtained figures quite so high as Professor Haldane had suggested—namely, 80 per cent.; he had occasionally got 75 or 76 per cent., but in most of the fatal cases he had investigated the figures were nearer 60 to 65 per cent. as an average. In very few cases had he found death occurring with a low percentage, and there could be little doubt that while a normal person required a very high percentage for a fatal dose a person in ill health might die with a very much lower percentage in the blood. He recalled the case of a young woman who committed suicide in this way, and in her case the saturation was only 45 per cent. She had with her a child of 7 who was unconscious but survived. The woman herself was suffering from advanced chronic tuberculosis of the lungs, and he thought the low fatal dose was occasioned by the fact that she would naturally offer less resistance than a healthy person. In two other cases in which the percentage was about 50 one was an old and feeble person, and the other was suffering from cancer of the ovary. With regard to the recognition of carbon monoxide in the body at

death, the post-mortem appearances were as Professor Haldane had pointed out, extremely characteristic, so that one could often diagnose a case of carbon monoxide poisoning on sight But there was one trap which might mislead a medical man not familiar with the changes which occurred A doctor, searching through the organs of the body, might find nothing at all to indicate the reason for death, and then be suddenly struck with the fact that the blood in the organs looked bright red, so that he would jump to the conclusion that it was a case of coal gas poisoning But that bright redness was entirely due to the changes in the viscera after exposure to air The blood in the viscera was of dark colour when first exposed, but after exposure it became a bright red One other form of poisoning in which sometimes the blood and even the viscera might have rather a bright colour was cyanide poisoning He thought that was almost the only condition in which the mistake was likely to be made

Mr MASTERMAN, *of the Gas Light and Coke Company*, mentioned that his company had made some tests on the carbon monoxide in the street atmosphere They had found that at mouth level, in a London street in ordinary traffic, there were about 20 parts of carbon monoxide per million, but that when, after a traffic block, the traffic was just restarting and the engines were accelerating the proportion went up to 60 parts

Professor HALDANE said that he wished the Gas Light and Coke Company would make similar experiments during a London fog because under those conditions the proportion of carbon monoxide was likely to be greatly increased

CARBON MONOXIDE POISONING

AT a meeting of the Aberdeen Medico Chirurgical Society on June 5th, with the president, Dr CHARLES FORBES, in the chair, Dr ROBERT RICHARDS made a communication on carbon monoxide poisoning, with special reference to its medico-legal significance

Dr Richards introduced his paper by saying that the whole subject of CO poisoning was intimately bound up with the question of suicide, and that the increase in the suicide rate had been a noteworthy characteristic of recent statistics in most countries and constituted a grave social problem The war years had been marked by a decrease in the suicide rate, but since that time the rate of increase had rapidly mounted In England and Wales, for example, in 1918 there were 2,765 deaths from suicide, and in 1928, 4,872, in Scotland for the same years the figures were 190 and 474 An extraordinary change in choice of method of suicide had also taken place during that period In Scotland and England the number of coal gas suicides had increased sixfold—in Scotland from 18 to 103, and in England from 176 to 1 088 Even in Aberdeen, although the figures were small practically the same increase had been seen—from 2 cases in 1919 to 14 in 1929 There were nearly as many coal gas suicides per year in Aberdeen as there were in the whole of Scotland in 1918 The increase had been greater in the female sex, for while gas suicides amounted to 23 per cent of all cases, the percentage among males was 19 5, contrasted with 28 6 among females The rise in suicidal cases was probably even greater than these figures showed, since many doubtful cases were attributed to accident from want of convincing proof of suicide Actually the deaths arising from purely accidental inhalation of coal gas during the same period had not increased *Accidental carbon monoxide poisoning* occurred from any apparatus where incomplete combustion resulted in the production of this gas—from coke stoves, geysers, explosives and motor-car exhausts—but the main source was from the domestic gas supply The recent report of the Departmental Committee of the Board of Trade on Deaths from Gas Poisoning gave the following list of possible causes of accident turning the wrong tap where two were close together, gas supplied from a pre-payment meter being left alight and becoming exhausted while the victim slept, and coins placed in the meter by some other person, drunkenness, absence of stop-pins, taps too loose, taps turned on when articles were hung on the gas bracket or removed therefrom, taps near the floor kicked on knocked by removing furniture, kettles or saucepans boiling over and extinguishing the flame, absence of sense of smell on the part of the victim Occasionally gas entered a dwelling by percolation through the floors from a burst main Accident could only be excluded by a survey of the attendant circumstances in each case, and it was known that accidental conditions could be simulated by a murderer, as could also evidence suggesting suicide The medico-legal question of whether a case was homicide, suicide, or accident was of some importance, and was likely to assume greater importance in the future

The CO content of coal gas constituted its one important toxic element The gas supply in different places contained varying proportions from 5 or 10 per cent to as high as 30 per cent, and statistics showed that the occurrence of asphyxiation rose in direct proportion to the CO content It was not commercially practicable or economical, however, to limit this constituent of the domestic supply, and such had been the finding of the Departmental Committee It had also been found impracticable to add any substance to gas which might quickly attract attention to escapes or render suicide more repellent, since any such irritant would affect normal consumers whenever the gas was turned on and left unlighted, even for a moment It would, moreover, tend to discourage the use of gas and might cause damage to fittings The toxic action of CO was due to its union with haemoglobin, thus depriving the tissues of oxygen The attraction of the haemoglobin for this gas was from 200 to 300 times that for oxygen, so that as long as carbon monoxide was present in the atmosphere it became fixed cumulatively in the blood From 20 to 30 per cent saturation of the haemoglobin produced headache and nausea, from 40 to 50 per cent collapse with inability to use the limbs, and over 55 per cent unconsciousness and rapid death The rate of elimination of CO from the blood stream in cases of survival was comparatively rapid, but varied with the percentage saturation Where this did not exceed 40 to 50 per cent, one-half of the gas was eliminated within an hour, as had been shown by Haldane and Henderson But where the saturation was sufficient to cause first hyperpnoea and then coma the rate of elimination was slow on account of the absence of respiratory movement and reduction of tissue carbon dioxide, which normally acted as a stimulus to respiration The rate of elimination had been of importance in medico-legal cases where delayed carbon monoxide poisoning had been claimed as the cause of death

Dr Richards discussed the diagnosis of carbon monoxide poisoning from the clinical aspect, and also demonstrated the usual tests for its presence in the blood—the dilution test, Kunkel's test, and the spectroscopic test He emphasized the importance of differentiating nitric oxide haemoglobin from carboxy-haemoglobin, since the possible presence of this substance was important from the medico-legal standpoint In conclusion, he gave an outline of the modern treatment of gas poisoning The primary object was to eliminate the CO from the blood with all possible speed, so curtailing prolonged asphyxial effects and consequent tissue damage This was best achieved by the inhalation method immediately upon removal from the toxic atmosphere, and a mixture of 7 per cent carbon dioxide and 93 per cent oxygen was recommended This treatment in America had given most dramatic results in cases of rapid asphyxiation occurring in firemen and blast furnace workers, who, though so nearly dead as to require artificial respiration, had by this means sufficiently recovered within twenty minutes as to be fit to return to duty

In the discussion which followed the paper it was agreed, on the suggestion of Professor Ashley W Mackintosh, to approach the local fire brigade and ambulance associations with a view to the provision of the necessary apparatus, cylinders of carbon dioxide, and oxygen for this purpose, and of facilities for the instruction of personnel in their use

THE DICK TEST IN PREGNANCY

At a meeting of the Edinburgh Obstetrical Society with the *president* Dr H S DAVIDSON, in the chair Dr DUGALD BAIRD and ROBERT CRUICKSHANK of Glasgow contributed a paper on the value of the Dick test in pregnancy

They said that during 1929 an investigation was conducted at the Glasgow Royal Maternity and Women's Hospital into the value of the Dick test—that is the cutaneous reaction to the intradermal injection of scarlatinal streptococcic toxin—as an index of susceptibility to puerperal sepsis Because of the generally accepted view that the toxins produced by the scarlatinal and puerperal haemolytic streptococci were identical, it was thought possible that sensitiveness to the one might indicate a similar degree of susceptibility to the other and if this were so, that the test might be of value in the prophylaxis of puerperal sepsis The Dick test was performed in a series of 600 pregnant women either during labour or in the last few weeks of pregnancy Careful histories were taken on cards designed for the purpose, particular note being made of previous streptococcal infection—for example scarlet fever tonsillitis puerperal sepsis—of the obstetric history, and of the health during the current pregnancy Full particulars were obtained later regarding the mode of delivery the presence of lacerations, and the puerperium in 500 of these cases, where the puerperium was morbid even although not notifiable according to the British Medical Association standard it was classed as puerperal sepsis, care being taken to eliminate those cases of pyrexia due to other causes, such as urinary infection A number of cases with a positive Dick test which developed pyrexia in the puerperium were retested immediately after the pyrexial period to see if any change in the reaction had occurred Some of these were again tested six months later They found that 22 per cent of pregnant women gave a positive reaction to the Dick test primiparae giving a slightly higher rate than multiparae—25 per cent as compared with 21 5 per cent The reaction seemed to be more intense in primiparae, irrespective of age, than in multiparae In the latter there was a decrease in the intensity of the reaction in the older age groups, which might indicate that with each pregnancy the patient had a chance, by repeated slight infection, of becoming more immune The incidence of puerperal morbidity also became less with advancing years in multiparae but remained constant for all ages in primiparae The incidence of puerperal sepsis was so dependent on the general health of the patient and upon the type of delivery that any reliance on the Dick test as an indication of liability to sepsis would not be justifiable It appeared, however that in the present state of obstetric practice an attempt to produce a temporary immunity with a concentrated anti-scarlet fever serum in all suspect cases at the time of delivery might reduce the incidence of puerperal sepsis

The Vaginal Flora in Pregnancy

This paper was followed by another contribution on a study of the vaginal flora in pregnancy by the same workers, Drs Baird and Cruickshank This investigation which had been carried out during the past two years, and was not yet completed, had been originally intended (*a*) to identify the bacterial flora of the vagina and the reaction of the vaginal secretion and to study the changes which they undergo as pregnancy advances and (*b*) to discover whether the character of the vaginal flora had a relation to the occurrence of puerperal sepsis The physiological changes in the flora of the vagina were first reviewed, special attention being drawn to the apparently dramatic change at puberty from a sparse coccal flora and an alkaline reaction to a flora consisting entirely of Döderlein's vaginal bacillus associated with a highly acid reaction of the vaginal secretion This change had been attributed by Miura, a Japanese worker to the deposition of glycogen in the superficial vaginal epithelium when ovulation began and the bacterial fermentation of the glycogen as glucose for the production of lactic acid in such concentration as to destroy all organisms save the aciduric Döderlein's bacillus Miura also stated that in pregnant women there was an increased acidity of the vaginal secretion as pregnancy advanced

The present investigation dealt with the vaginal flora of 200 pregnant women a large proportion of whom attended at monthly intervals from the third month of pregnancy until term. Swabs were taken from the vaginal vault and smears and cultures made The *p*H of the vaginal secretion which was collected at the same time with a long handled spoon was estimated by the colorimetric method

A classification into three grades of vaginal flora was made Grade A composed entirely of Doderlein bacilli the *p*H of secretion varying only from 4·0 to 4·4 Grade B consisting of a mixture of Doderlein's bacillus and diphtheroids *p*H 4·6 to 5·2 and Grade C consisting of an abundant heterogenous flora of diphtheroids cocci rod-shaped cocci and occasionally fusiform and coliform bacilli *p*H 4·8 to 6·8 with a more common range of 5·2 to 5·6 Large epithelial cells were particularly numerous in Grade A flora

Of 200 pregnant women when first seen 55 per cent had Grade A flora 10 per cent Grade B and 35 per cent Grade C Of the women who were followed throughout pregnancy there was found a remarkable constancy in the vaginal flora and in the *p*H of the vaginal secretion in those cases with Grade A flora The women with Grade B or Grade C flora were likely to show with pus cells in the vaginal smear an abnormal amount of infection of the cervix or vagina—and a group with idiopathic Grade C flora—that is an abundant mixed bacterial flora with pus cells The flora in the former group remained Grade B or Grade C throughout but in the latter group the flora changed from Grade C to Grade A in twenty-three of 21 cases This change from the improvement occurring usually about the middle of the fourth month of pregnancy

The theory was formed that there existed some relationship between the vaginal flora and ovarian activity a Grade A flora being a reflex of actively functioning ovaries whereas hypo-ovarianism is reflected in a Grade C flora The association of an idiopathic Grade C flora with greater pain and with a tendency to repeated abortion and the change over from a Grade C to Grade A flora during pregnancy were findings which support this view No evidence had been found to indicate that a Grade C flora increased the susceptibility to puerperal sepsis but the number of women examined was still too small to allow of definite conclusion

MENSTRUATION IN SCHOOLGIRLS

At a recent meeting of the London Association of the Medical Women's Federation a report on an inquiry into menstruation in schoolgirls based on over 6 000 replies to a questionary by a committee of the association was presented to, and passed by the association The following is a summary of the information derived from the questionary

The distribution of the interval between the periods is peculiar and suggests a predilection for whole weeks—that is the frequencies recorded at 21 28 and 35 days seem exceptionally high The most frequently occurring interval is centred on 28 days

The presence or absence of pain does not seem to be sensibly correlated with length of interval

The regularity of the period is significantly but slightly related to pain the proportion recorded as regular being greater in the *no* pain group than in all others

The average duration of the period is definitely but slightly lower among girls taking full exercise throughout the period

The duration is longer (about one-third of a day) in those who suffer pain than in those who do not

Slightly more than half of the girls studied do not suffer pain or discomfort however slight at any time during the menstrual period

Of those recorded as suffering pain the majority suffer *during* the period only

The differences in the incidence of pain in the three groups of schools (high, secondary and boarding schools) when analysed separately are not very large

The distribution of the number of girls taking full exercise throughout the period in the three groups of schools [illegible] considerable differences and contrasts with the great similarity of degrees between the group of girls in respect of [illegible] pain.

Pain and exercise seem to be definitely [illegible] but from these data it is impossible to [illegible] and which is effect

The incidence of disturbed happiness [illegible] ache and constipation is [illegible] of pain the influence being [illegible] disturbed health and happiness and constipation

Absence from school is definitely related to the occurrence of pain, but regular or frequent absence is very rare at any time during adolescence

The time in the menstrual cycle at which the pain occurs is related to all the above factors The incidence of all of them increases steadily and gradually in the following order with no pain, pain before the period, during the period, after, and before, during, and after the period

Comparison of the whole series and that obtained by excluding girls with a history of one year or less suggests that at the early period of menstruation a smaller proportion of girls suffer pain than later, during the age period studied (onset to 18)

Analysis of the whole series by years shows that the rise of incidence of pain is steady and gradual throughout the menstrual histories studied The rate increase over 8 years is less than three times the original value

The incidence of disturbed general health and happiness also increases progressively with length of menstrual history

Irregularity definitely decreases in incidence with increasing length of history

The average duration of the period shows no tendency to rise or fall with increasing length of history

The details of the investigation, and a commentary on its results, will shortly be published

CANCER OF THE UTERUS

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held in Dublin at the Royal College of Physicians, with the president, Professor A H DAVIDSON, in the chair, Dr NINIAN FALKINER demonstrated a specimen from a case of carcinoma of the cervix complicating pregnancy

The patient, aged 39, married fifteen years, having eleven children, the last in January, 1929, was admitted on January 29th, 1930, complaining of bleeding, something coming down, and frequency of micturition Menstruation had been regular, and the last period had taken place on January 15th There had been a particularly heavy bleeding on January 1st General examination revealed a wasted anaemic patient weighing 6 st 7 lb Her red blood corpuscles numbered 3,500,000, and her haemoglobin was 60 per cent On parting the labia and introitus a fungating mass could be seen arising from the cervix, no bluing was noted The uterus was enlarged, and the growth could be felt implicating the utero-sacral ligaments Carcinoma of the cervix was diagnosed, and the enlargement of the uterus was put down to pyometra At operation the uterus was seen to be enlarged, but this condition was thought to be due to pyometra, and hysterectomy was proceeded with The bladder could not be pushed down, and a total operation was done instead of the Wertheim On the fifteenth day the patient complained of difficulty in holding her water Examination revealed a vesico vaginal fistula She had deep x ray therapy and left hospital feeling well, and is to return in a few months for re examination The specimen was examined after removal and the following report was received Carcinoma of the cervix, squamous cell in type, pregnant uterus containing a three months foetus, some haemorrhage from placenta, ovary contains corpus luteum of pregnancy

Dr BETHEL SOLOMONS showed two specimens of uterine cancer

The first had been taken from a patient, aged 45, single, who had complained of a sanguineous discharge, which sometimes became offensive, for seven or eight months She was otherwise healthy, except that she had become stout Examination revealed a small, hard uterus, and, the cervix being healthy, subtotal hysterectomy was done The uterus was opened immediately, and as it was obviously malignant the cervix was removed with [illegible] had been greater [illegible] made an uninterrupted recovery

[illegible] amounted to 23 per cent of [illegible] of case brought up [illegible] both adnexa The [illegible] contrasted with 28.6 among [illegible]

Dr Solomons said that this type [illegible] the important question what was the correct treatment for a woman who desired to get well in the shortest possible time when there was doubt about the diagnosis—and in this case there was much doubt, as the uterus felt infantile He believed that the treatment he had followed was the best A preliminary curettage would have delayed matters, a total hysterectomy was unnecessary, because the cervix was normal, and the diagnosis of malignant disease was impossible until the uterus was opened

Dr Bourke's report of the specimen was as follows

Macroscopically the cervix shows a pearly, greyish mass, extending from the lumen and infiltrating the wall in a parallel line, it measures almost a quarter of an inch The cavity of the uterus presents a rugged verrucose surface The endometrium on cross section appears greyish white in colour and slightly uneven

Microscopically the cervix shows dense infiltration of the wall by solid [illegible] like masses of epithelial cells, there is no keratinization This is a solid carcinoma of low malignancy. The uterus presents a picture of massive hypertrophy of the glandular tissue, in some places the stroma is replaced by solid masses of cells similar to those seen in the cervix This is apparently an extension upwards of the malignant process originating in the cervix From this the condition is either one of adenocarcinoma of the cervix spreading upwards or of the body of the uterus spreading downwards

Adenocarcinoma of the cervix in a nulliparous unmarried woman, said Dr Solomons, was most unusual Adenocarcinoma with a uterus comparable to one of infantile type was also unusual Cervical adenocarcinoma might spread in either direction Corporeal carcinoma was most likely to make its way towards the abdominal cavity

The second specimen shown by Dr Solomons was of a uterus containing an enormous cervical carcinoma, which he had removed from a pregnant woman, aged 28—a 5-para who had had four healthy children

The patient was admitted complaining of a foul-smelling discharge, and appeared ill The foetus was about 28 weeks, and the foetal heart was audible On vaginal examination a freely bleeding cauliflower mass was discovered springing from the cervix The os was about four fingers dilated and the membranes were ruptured Believing that fatal haemorrhage would occur if the patient was delivered vaginally, Caesarean section was decided on The uterus was opened, after which it was intended to remove the infant, and then the placenta *in situ*, but as the latter presented it was speedily removed, after which a live baby weighing 2 lb 13 oz was delivered The head showed a marked caput succedaneum, caused by the definite disproportion set up by the enormous growth It was then found that the tumour was of a size larger than a clenched fist, and that it had retracted high over the head, total hysterectomy was quickly done The patient recovered from the immediate effects of the operation and left the hospital The infant has put on weight and appears likely to live The pathological report was as follows

Macroscopically the uterus is enlarged, and shows a recent operation wound on its anterior aspect, it corresponds to the post-partum uterus There is a large cauliflower like mass springing from the external os, on opening the cavity the uterus is full of blood clot, but presents no other abnormality The tumour at the cervix is white in colour, on section it is outlined from the cervical tissue

Microscopically sections show solid columns of rather large cells closely packed together and infiltrating the surrounding tissues There are no cell nests present, but from the appearance of the cells and their arrangement there can be no doubt that this growth originated from the squamous epithelium of the portio, the line of cleavage between the malignant process and the cervical tissue is well marked, and is surrounded by a zone of small round-celled infiltration The cervical tissue towards the uterus shows scattered areas of round-celled infiltration

UREA CONCENTRATION TEST

THE fourth summer meeting of the Association of Clinical Pathologists was held at the Cheltenham General and Eye Hospital on June 14th with Dr J B DAVEY in the chair Dr T C HUNT described a combination of a water excretion and urea concentration test for renal function Dr S C DYKE gave a brief preliminary report upon the phosphate concentration test of Brain and Kay for estimation of renal function, the speaker had found the test somewhat unwieldy for ordinary clinical use Dr A F S SLADDEN, discussing the importance of the urinary acid ammonia ratio as an index of renal health, pointed out that this ratio was extremely constant, and that any departure from the normal in the absence of alkali therapy was an indication of disturbed renal function Dr DYKE opened a discussion on the urea concentration test, in the course of which he asked at what stage of the test a specimen of blood for estimation of urea should be taken, opinion differed widely on this point The speaker stated that inasmuch as [illegible] solution [illegible] ink as one of the concentrating power of the [illegible] he regarded [illegible] always to take the blood kidneys, it had been his custom [illegible] the results of at the third hour Dr J B DAVEY reviewed the urea concentration test as an indication for complete prostatectomy In the course of the afternoon session demonstrations were given as follows Dr A RENSHAW a self filling burette for routine analytical work, a new type of chamber for counting the cells of the blood, and other technical devices Dr DYKE mice showing results of Zondek Aschheim test for pregnancy Dr A L TAYLOR recent additions to the pathological museum of the British General Hospital Dr E N DAVEY pathological specimens from the Gloucester General Hospital, and an unusual type of typhoid bacillus isolated from a suppurating mesenteric cyst Dr J R COLLINS, senior physician to the Cheltenham Hospital, addressed the members on the "Sins of the pathologist" In the course of the evening a party of members was shown round the baths by Mr T Holmes, senior surgeon to the hospital

Reviews.

THE CEREBRO-SPINAL FLUID

In his monograph on the cerebro spinal fluid[1] Dr Riser has summarized the work done and the results obtained by the Toulouse school of neurology during the past ten years In describing the methods adopted for obtaining access to the cerebro-spinal fluid spaces via the different avenues of approach, he has made very useful practical suggestions, which are the fruit of a large number of observations The pitfalls the complications, and the abnormal sequels of lumbar and cisternal puncture are carefully outlined The methods of biochemical examination of the fluid are only briefly mentioned, the author being more concerned to point out the clinical bearing of those experimental researches into the origin, circulation, and absorption of the fluid which have been carried on by his colleagues Observations upon experimental and acquired hydrocephalus have led him to the view that the pial capillaries cannot be credited with any contribution to the fluid this probably all comes from the choroid plexuses whose epithelium is endowed with no selective permeability He holds that there is a continuous circulation of the fluid from the ventricles to the spinal cord but that nowhere does it come into intimate contact with the cells of the central nervous system Therefore drugs which may be introduced into it, either from the blood stream or by direct injection do not reach further than the most superficial layer of the brain and spinal cord Absorption of the fluid he finds, is by the veins, and not to any noteworthy extent by the lymphatics

For the localization of spinal cord lesions associated with interruption of the intrathecal circulation, as by a tumour, Dr Riser advocates the use of a heavy lipiodol solution injected into the lumbar region After the injection the patient is placed prone upon a horizontal table which is then tipped so as to bring the head lower than the pelvis The lipiodol then flows towards the skull, and its level of arrest, when this occurs gives the lower level of the obstruction This method, he claims, has the advantage that the comparatively hazardous operations of cervical or cisternal puncture are avoided and that the lipiodol, if arrested in this up-side-down position of the patient, returns to the lumbar region when the normal erect position is regained, and does not remain as a source of irritation in contact with the obstructing mass Further, if, after a single lumbar injection of lipiodol a level of imperfect or suspected arrest is made out, the patient may be again placed in the inverted position on subsequent days and the level of arrest confirmed as often as may be desired without further injection When the lipiodol passes upwards into the base of the skull no untoward effects have been noticed, and it all returns to the lumbar region when the patient is sat up The occasional disadvantages of this technique are discussed, it has much to recommend it, and has not been as widely used as it deserves The concluding chapter gives a summary of the cerebro spinal fluid reactions in those pathological conditions in which its analysis gives most information However, the information which it does or may afford is not set down although the methods suggested for use in each case are given

What Dr Riser has to say has been said clearly and concisely It is not unnatural that local bias in favour of his fellow workers' results should show itself in places, but on the whole conflicting evidence is faithfully dealt with, and his conclusions and recommendations will be generally accepted The book is a valuable contribution to this subject

SURGICAL ASPECTS OF OTOLOGY

Otologic Surgery,[2] by Dr SAMUEL J KOPETZKY of New York, fills a useful place in the literature of otology, being directed to its purely surgical aspect It should appeal especially to those recently placed in charge of aural clinics and to those numerous general surgeons who either from necessity or choice include operations on the ear in their practice The surgical treatment of new growths and of facial paralysis are not included, and these may be regarded as on the fringe of the subject and not strictly within the scope indicated Otherwise the reader will find a modern and convincing presentation of all that relates to the surgery of the ear Dr Kopetzky lays a sound basis of surgical pathology upon which he builds the various methods of treatment so that we are presented with a book whose claims can be advocated without reserve although the value of some therapeutic details might be the subject of varied opinions

In the chapter devoted to the simple mastoid operation the pathology of acute otitis media and its extension to the mastoid process is described in a masterly fashion The author describes two types—the coalescent and haemorrhagic types of mastoiditis—which must be familiar to all aural surgeons though not always clearly recognized as separate clinical and pathological condition He traces skilfully the importance of these in relation to blood infections which are described in the chapter on otogenous pyæmic infections including sinus thrombosis Great importance is attached to examinations of the blood and in particular to estimations of the haemoglobin content The author advocates transfusion of whole blood when the haemoglobin percentage has dropped to 55, owing to blood destruction by the haemolytic streptococcus He evidently attaches even greater importance to laboratory tests than is usual in this country but he shows good reasons for this and devotes a valuable chapter at the end to this matter There is a clear description of the radical mastoid operation, with its numerous pitfalls and excellent advice in the management of these common but really difficult cases In the chapter on meningitis the Haynes-Kopetzky operation of trephining the occipital bone to drain the cisterna magna is described and advocated Although this operation presents some superficial attractions it never succeeds and we feel that it should no longer be advocated implying that something may be done for the patient Dr Kopetzky however, has made such valuable contributions to the study of meningitis that this chapter is one of the most fascinating The chapter on brain abscess gives useful information in the diagnosis and treatment of the condition, but is somehow lacks the personal authority which is conveyed elsewhere in the book at first hand

There are a few literary blemishes such as the persistent use of the word drum for the tympanic membrane instead of the tympanum but the writing on the whole makes pleasant and smooth reading The book is a valuable contribution to the literature of otology, and will repay careful study by every aural surgeon

PHYSICAL EXAMINATION OF THE LUNGS

SHOULD the diagnosis of diseases of the chest be sought for by inductive or by deductive methods Dr KRAETZER in his book *Procedure in Examination of the Lungs*[3] is emphatically in favour of induction It is very doubtful if a hard-and-fast choice of either method could be made for the whole art of diagnosis, and even the author, in his last chapter admits that in the case of pulmonary tuberculosis deductive methods must be used But as a method of learning the art of physical examination of the chest, in so far as this relates to diagnosis and for the foundation training of students in this branch of medicine Dr Kraetzer establishes his case for induction It is an excellent little book written in American rather than English which is perhaps an advantage for there is not a sentence in it that will leave the reader in doubt of what the author wishes him to learn from it At first sight the scheme of physical examination suggested seems rather muddled but only because it differs from the conventional system, and a little thought will show it to be both logical and thorough There is a refreshing personal flavour running through the whole book the student who

[3] *Procedure in Examination of the Lungs* By Arthur F Kraetzer MD With a foreword by James Alexander Miller LD Oxford Medical Publications London and New York Milford Oxford University Press 1930 (5¼ × 8¼ pp xiv + 125 15 figures 6s net)

reads it will find himself in the presence of a quick-tempered and emphatic chief, a "real, sure enough, honest-to-goodness" teacher, rather scathing about the inanities that he has heard repeated year after year by his successive classes, but keenly sympathetic to real difficulty, and full of encouragement for the slow and painstaking. The book can be warmly recommended to all training schools. It may contain many conclusions with which other physicians might disagree but this is unimportant, since the foundation and main structure are exceedingly sound.

PSYCHOLOGY

A VOLUME entitled *Psychology Normal and Abnormal*,[4] by DR J. W. BRIDGES, professor of psychology in the Faculty of Medicine of McGill University, is written with special reference to the needs of the medical student and practitioner. The author observes that, while the colleges at present generally recognize the importance of psychology in the medical curriculum, no suitable textbook is yet available for a course for medical students. This book is an attempt to meet the requirements of such a course, and on the whole it would seem that Dr. Bridges has adequately carried out his by no means easy task. The subject-matter has been judiciously selected, and the book provides the student with a sufficiently concise and comprehensive outline of psychological teaching, both theoretical and applied, to meet his needs. Those who aspire to a diploma in psychological medicine, and who have had no previous grounding in the elements of psychology, will probably find this volume helpful as an introductory textbook, though it will no doubt be necessary for them to consult also more advanced and specialized works.

The Psychology of the Adolescent[5] by DR LETA HOLLINGWORTH, professor of education, Teachers College, Columbia University, is a thoughtful, admirably written, and well-balanced book, which will be studied with advantage by parents and teachers. The author writes objectively and lucidly, and does not confuse the mind of the reader by discussing the theories of the various psychological schools or by the use of unnecessary technical language. A good case is made out in this book for the desirability of educated parents making themselves acquainted with the problems of adolescence. As the writer observes, to have been an adolescent some years ago is not necessarily, or even probably, to remember what an adolescent is like. To have been an infant is not to know what an infant's problems are. Each of the developmental periods of life brings its own characteristic problems, minimizing and obscuring those which preceded. Therefore parents, being themselves engrossed with the problems peculiar to maturity, realize but dimly the adjustments through which the boy or girl in the "teens" is passing. The information conveyed in this book is certainly of a kind to assist parents and teachers to gain increased insight into the problems, aspirations, outlook, and vocational possibilities of the young people for whose guidance or education they may be responsible.

In a volume on *The Science of Living*[6] DR ALFRED ADLER endeavours to show how the psychological principles he has elaborated have a practical bearing upon the problems of the individual in relation to his work, social environment, and sex life. Here, as in his other works, the author, with considerable skill and ingenuity, though not always quite convincingly, endeavours to interpret human activities, both normal and abnormal, as a struggle against a sense of inferiority—and, conversely, as a striving to gain a position of superiority. MR PHILIPPE MAIRET writes an introductory note to this volume, in which he explains the pedagogic and social aims of the Individual Psychology Movement, of which Dr. Adler is the founder.

AN OUTLINE OF R.A.M.C. HISTORY

A SCOTTISH member of Parliament, criticizing the manner in which history is taught, declared recently that in the pageant of events too much attention has been given to battle and sudden death, and to the pomp and circumstance surrounding the thrones of certain royal filibusters, while the passage of great social reforms and the gradual betterment of the conditions of the common folk have been largely ignored. After studying *A Short History of the Army Medical Corps*[7] the non-military reader may be inclined to think that there is something in this point of view. Colonel FRED SMITH has set out to tell the tale of the gradual development of the medical services of the British Army, from the days when there were no standing armies up to the present day. In a memorandum he carefully defines the scope of the book. It is written for the use of young soldiers of the R.A.M.C. for examination purposes, and within the compass of ten short chapters—111 pages—*the tale is acceptably told.* The various changes from one uniform to another, the alterations in the title of the Service, and the adoption of new methods of organization are carefully chronicled. These are interesting in their way, but it is doubtful whether they are of outstanding importance from an examination point of view.

A great part of the book is devoted to records of the award of the Victoria Cross and other decorations to members of the corps. It is well that these deeds of gallantry should not be forgotten, it might, however, be less confusing to the examination candidate if their record was placed in an appendix. The importance of history lies mainly in the lessons that it teaches. The devastating incidence of disease in previous campaigns and its gradual decrease with the enhanced knowledge and wider powers of the medical services should be brought to the young soldier's notice. How better could this be done than through the page of history? In the interesting account of the typhus epidemic at Wittenberg Camp the award of the D.S.O. is carefully chronicled. It should not be forgotten that the Royal College of Physicians of Edinburgh offered its Membership without fee or examination to Major Priestley and Captains Vidal and Laudor. The record of the Special Reserve and the Territorial R.A.M.C. in the great war is dismissed by Colonel Smith in three-quarters of a page. The Haldane Scheme and the activities of the Territorial Army since the war are not mentioned. Yet Territorial officers are being constantly told that in the next war the mistake of Kitchener's Army will not be repeated, and that all development will be through the auxiliary forces as at present constituted. The Army Dental Service is given half a line. So important was this service considered during the war that at least one of the oversea Dominions considered organizing a special dental department, independent of the medical services.

There is a definite demand for a book such as Colonel Fred Smith has written, and those interested in the training of R.A.M.C. soldiers in the different branches of His Majesty's Forces will welcome its appearance. With a little rearrangement, amplification here, and curtailment there, the value of this little history might be greatly increased.

NOTES ON BOOKS

A *Synopsis of Surgery*, by Professor E. W. HEY GROVES, maintains its place both as a handy work of reference for the busy practitioner and as a valuable guide to the student entering on his final examination. In preparing the ninth edition[8] the author has carefully revised the whole text and brought it up to date. It is perhaps inevitable in a work presenting so many facts that values should be neglected. The author refers, for example, to Trendelenburg's operation and to the method of multiple excision and ligature in the treatment of varicose veins, and describes briefly the treatment by injection of sclerosing fluids. But he expresses no preferences, he neither

[7] *A Short History of the Royal Army Medical Corps.* By Colonel Fred Smith, C.B., C.M.G., D.S.O., R.A.M.C. (retired pay). Aldershot: Gale and Polden, Ltd. 1930. (Cr. 8vo, pp. 111. 5 plates. Paper cover, 1s. 6d. net; cloth, 2s. 6d. net.)

[8] *A Synopsis of Surgery.* By Ernest W. Hey Groves, M.S., M.D. Bris., F.R.C.S. Ninth edition. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (Cr. 8vo, pp. viii + 676, 148 figures, 13 plates. 17s. 6d. net.)

evaluates the methods, nor does he present data from which the student might assess their relative merits for himself. The section on the use of radium in the treatment of malignant disease is far too brief to be helpful. Professor Hey Groves has had to face the fact that the whole of general surgery cannot be compressed into a volume of under 700 pages, but we think it a pity that in throwing overboard all except necessities he should have sacrificed a subject of such growing importance as radium therapy. From every other aspect his work, whether in the choice and arrangement of material or in the manner of presentation, is as good as a synopsis of a large subject can be.

The *Treatise on Materia Medica and Therapeutics*[9] by the late Rakhaldas Ghosh made its first appearance nearly thirty years ago, and since then it has passed through no fewer than twelve editions under the editorship in succession of the late Sir Pardey Lukis, Lieut.-Colonel J. T. Calvert, Lieut.-Colonel H. B. Deare, and Dr. B. N. Ghosh. The latest issue of this deservedly popular textbook bears evidence of careful revision, many parts have been rewritten, and almost every drug has received attention in the light of recent pharmacological research. We note, however, that in the copy received for review pages 657 to 672 inclusive are *not in their right* place, but have been bound up between pages 640 and 641.

In his little work on the Diagnosis of Acute Sore Throat[10] which forms part of the series entitled 'Médecine et chirurgie pratiques,' Professor A. B. Marfan has *two objects in view*: first, to show how by clinical examination alone it is possible to decide whether in any case of acute sore throat diphtheria antitoxin should be given at once or not; and, secondly, to revise the nosography of acute sore throat. According to Professor Marfan the groups of symptoms by which the diagnosis of the nature of an acute sore throat is established are, in order of importance, first the appearance of the throat itself, secondly the associated local phenomena such as laryngitis, discharge from the nose, and enlargement of the cervical glands, and, thirdly, the degree of constitutional disturbance. Sore throats are divided by the author into red and white according as they are merely catarrhal or show more or less deposit, as in diphtheria, scarlet fever, syphilis, tonsillitis, quinsy, and Vincent's angina. These clinical distinctions are followed by short chapters on the bacteriological diagnosis of acute sore throat.

Salvaging Old Age[11] by Dr. J. J. Martin and Mr. Claire de Gruchy, is a book of wise advice to those who are dreading enforced retirement. Dr. Martin, who is in his eightieth year, began to think on these things *when he was 40, and he holds* clinics for the benefit of those who do not enjoy their later days. The tragedy of old age is unhappiness, and out of *more than two hundred old people studied not more than three* could be called even contented. The psychological factors responsible for this unfortunate state of mind are analysed before the consideration of the *psychological methods recommended* as remedial treatment. The suggestion by relatives, children, and grandchildren that their seniors are senile must be prevented, and the conduct, well meant though it may be, of the young in assuming responsibility for their elders is deleterious. For their sake the old must school themselves in voluntary effort in observation and re-education of the memory. Dr. Martin shows that there is plenty of useful work for the old. He himself learnt to drive a motor car and obtained an operator's licence when he was 77 years old, and he holds up the more wonderful instance of a man of 95 who did the same in three days.

South America has become more and more important to the business man, the investor, and the traveller, and *The South American Handbook, 1930*[12] edited by H. D. Davies, provides information suited to the requirements of all of these. It claims to put South America in a nutshell, and certainly a vast amount of information has been compressed within its cover. It will interest medical men as investors and travellers rather than in their professional capacity, for it contains no information about the possibilities of practising their craft in these flourishing countries. The fact that the work has reached a seventh edition shows that it is meeting the needs of a great number of readers.

[9] *A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology and Administration of Drugs.* By the late Rakhaldas Ghosh. Twelfth edition by Birendra Nath Ghosh, F.R.F.P. and S. Calcutta: Hilton and Co.; London: H. K. Lewis and Co. Ltd. 1930. (Cr. 8vo, pp. xii + 765. 12s. 6d. net. Rs. 7/8 or 12s. 6d.)

PREPARATIONS AND APPLIANCES

Gonorrhœa in the Female Child

Dr. Harold G. Broadbridge (clinical assistant, genito-urinary department, London Hospital) sends particulars of the following apparatus for use in the treatment of gonorrhœa in female children. He writes:

The cannulæ here illustrated were designed to facilitate the local application of lotions, paints, etc., to the child's urethra and vagina—particularly in gonococcal infection.

The urethral cannula is probe-pointed at one end, while the other end receives a small nipple fitting. When the cannula is in use a piece of narrow rubber tubing, eight inches long, fitted with a male nipple, connects it with a stopcock in the tubing of an ordinary irrigation jar (Fig. 1). The cannula is introduced into the urethra *with the lotion flowing*, and the stream is maintained, while the cannula moves gently up and down the urethra. If it is desired to leave some of the lotion in the bladder, or to be retained later on, and so to flush out the urethra (a method often used in adult women), it is only necessary to pass the cannula on into the bladder—the stream of lotion being continuous.

For paints such as solutions of silver nitrate, a 1 c.cm. Record *syringe replaces the stopcock* in the rubber tubing (Fig. 2). In this case the unattached cannula is passed through the urethra until its probe point enters the bladder, as shown by the appearance of a few drops of urine at its other end. The cannula is then withdrawn into the urethra just sufficiently to prevent the escape of urine. The syringe, narrow tubing, and nipple are charged with the paint or application, and the nipple is attached to the cannula, which is already in position. As the syringe is slowly emptied the cannula is very gradually drawn along the urethra and out. The syringe must be filled with the narrow tubing attached, as otherwise the solution will simply expelled into the empty rubber tubing and only air reaches the urethra.

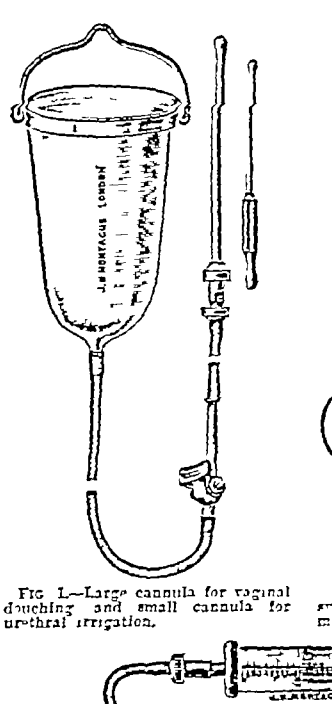

FIG. 1.—Large cannula for vaginal douching and small cannula for urethral irrigation.

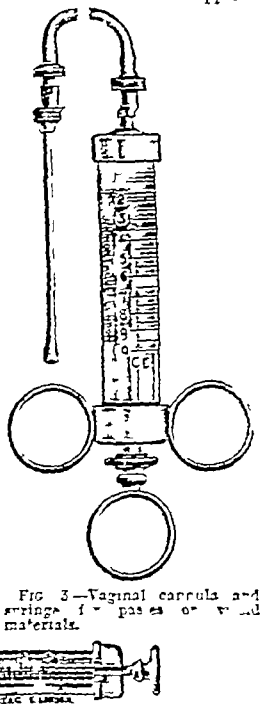

FIG. 3.—Vaginal cannula and syringe for passage of viscid materials.

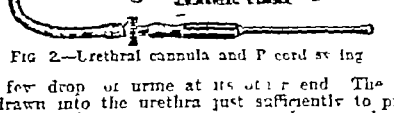

FIG. 2.—Urethral cannula and Record syringe.

The vaginal cannulæ are of two varieties: one with a spray nozzle for douching (Fig. 1), and the other with a wide-bore aperture for the introduction into the vaginal *fornices* of viscid materials—for example 2 per cent. flavine in glycerin (Fig. 3). This last cannula is connected with a 10 c.cm. syringe by narrow tubing fitted with nipples—*the nipples in this case having barbed* catches.

In using these instruments *the following* facts should be borne in mind: (1) *Eight inches of narrow tubing* allows the cannula to be a long way from the supply of lotion. (2) *The introducing* hand may be rested firmly against the buttock. Should the child make any unexpected movement the cannula narrow tubing and hand of the operator will all move *with* the buttock, thus avoiding any risk of injury. The passage of these cannulæ into the urethra or vagina of a child causes little if any discomfort, and enables a complete antiseptic treatment to be given.

My thanks are due to Mr. Hugh Lett, senior surgeon to the London Hospital and director of the genito-urinary department of the hospital for kindly allowing this work to be carried on in the department. The instruments are made by Mr. J. H. Montague of Bond Street, W., and may be obtained singly or as a complete outfit.

ROYAL SANITARY INSTITUTE CONGRESS

THE congress of the Royal Sanitary Institute at Margate, some of the earlier proceedings of which were recorded in our last issue (p. 1182), continued its sessions until June 28th.

Maternal Mortality

In the Maternity and Child Welfare Section a discussion took place on the latest scientific advances in regard to maternal mortality. DAME LOUISE MCILROY, dealing with the influence of criminal abortion on maternal mortality and morbidity, pointed out how little the medical profession could do to stop the practice owing to the oath not to reveal the confidences of a patient. The remedies she envisaged were a better moral outlook and a realization of the dangers of abortion and its effect upon life and health. Confidential notification of all cases of abortion would give some idea of the prevalence of the condition, and as all cases of septic abortion were notified already it should not be difficult to obtain notification of every abortion. Another necessary measure was the suppression of all advertisements of drugs sold for the purpose of inducing abortion no matter how they were labelled.

MR. C. S. LANE ROBERTS discussed the scope of prevention in obstetrics and the chief points to be observed in the avoidance of puerperal sepsis, and DR. LEONARD COLEBROOK followed with a paper on the bacteriological aspects of puerperal fever. He remarked that three years ago he would have said that the issue was narrowed down to one type of streptococcus—namely the haemolytic variety. But in Germany it had been found that quite a different type of streptococcus must also be taken into account—namely the anaerobic variety—and he himself was now convinced that his former scepticism was wrong, and that it was necessary to guard against both these dangerous types of organism. Unfortunately the recognition of the anaerobic streptococcus was going to add considerably to the difficulty because it was not a single well-defined type but a complex group, and several years of research would be required to learn all about the different members of the group.

Training and Employment of Midwives

In another section DR. ETHEL CASSIE, chief medical officer for maternity and child welfare, Birmingham, discussed the relations of the midwife with the public health authority, and cited experience in Holland and Denmark, where she said, midwifery results were greatly in advance of British. It was not only the fact that the midwives were much better trained, nor that every labour was attended by a midwife, it was, above all, that the midwife was recognized by the doctors as the proper person to undertake a normal delivery, while the doctors were trained almost exclusively for abnormal work. DR. J. E. SPENCE (M.O.H., Eccles) also addressed the congress on the same subject. He pointed out that about 660,000 births occurred annually in England and Wales, of which, under an adequate midwifery service, probably 500,000 would be attended by midwives. He estimated that a whole-time midwife could take 70 cases a year, which would mean that 7,000 midwives were necessary to carry on the service for the whole country. A fresh supply of 1,000 midwives would be required each year to recruit the service. In 1928 the number who entered for the examination of the Central Midwives Board was 2,811, of whom 1,730 were possessed of a general nursing training and the majority of these nurse-midwives found more attractive and lucrative occupation in nursing than in the midwifery service. The solution of the problem was to make the conditions of service in the midwifery profession more attractive and to improve the remuneration so that an efficient whole-time service could be built up.

National Health Insurance Medical Service

In a conference on this subject, DR. ALFRED COX, Medical Secretary British Medical Association, spoke on seventeen years' experience of the National Health Insurance Medical Service. He remarked that the common newspaper complaint against the service was to the effect that it was not something which it had never pretended to be. MR. LLOYD GEORGE told the profession at the outset that he was aware that his scheme was incomplete, but that half a loaf was better than no bread, and he proposed to start with a general practitioner service. Nothing much had been added to that foundation because the scheme had never yet had a really normal year, what with the war, demobilization, disastrous labour disputes, and now phenomenal unemployment. But the system had provided a general practitioner service which he believed, had been of great benefit to the community, the insured person, and the medical profession, although, like all human institutions it had its weaknesses. From a study of other national insurance systems, he was sure that the British system worked with greater ease and less complaint on the part of doctors and patients than any other compulsory insurance known to him. The politician, never particularly noticeable in the local administration of the British system, had a sinister influence in many other countries. Some hundred doctors whom he had consulted, and whose practice dated from pre-insurance days, nearly all agreed that the medical service now being given was much superior; all rejoiced in their ability to give a proper service without having to think about the bill, all agreed that insured persons resorted much more freely to the doctor in the early stages of disease, and that the prejudice against the system, very marked in the early days, had almost disappeared. With regard to the effect on the medical profession, the service had enlisted the organized profession as a vital part of its machinery, and thus had provided a valuable training ground in public service. It had caused the tendency to partnership greatly to increase, and had made for a more equitable distribution of the profession. The only serious substitute was a State medical service which would be devoid of the human touch so necessary in family practice.

The subject of the insurance practitioner was also alluded to in another paper read before the congress by MISS HESTER VINCE, who urged the extension of the system to the families of wage-earners, and that the insurance practitioner should undertake complete medical examinations of every member of the family at least three times every year, the results to be carefully recorded.

Hygiene in the Home and in Industry

SIR FRANCIS GOODENOUGH presiding over the section which dealt with hygiene in industry, drew attention to some problems of hygienic heating, especially the tendency of builders to erect small houses with one or more rooms unprovided with any flue. This was actually done by some local authorities for the purpose of encouraging the use of electric heaters, but in very many cases the cost of electric heating drove the tenant to buy an oil stove or cheap flueless gas stove, neither of which was satisfactory or even safe, while the electric heater had no ventilating effect, and only created "fug" in a flueless room.

DR. H. M. VERNON of the Industrial Research Board spoke on methods of investigating and improving the health of industrial workers, and mentioned that a scheme was under consideration for a compulsory periodical medical examination of all workers engaged in the trades which involved the inhalation of silica containing dust.

DR. MILIAIS CULPIN, in a very interesting paper described some occupational neuroses, and remarked on the erratic character of the sickness rates in different industrial establishments. He mentioned one large manufacturing firm with excellent welfare arrangements and its own medical staff, which had one of the highest sickness rates encountered—up to 16·48 days for females over 22—and of this high sick rate 14·9 per cent was due to dysmenorrhoea. On the other hand, a large retail store, where about half the staff were females had a sickness rate of only 2·6 days, and of this only 1/2 to 1 per cent was due to dysmenorrhoea. It was a curious contrast for which he defied the gynaecologists to supply a satisfactory reason. Dr. Culpin dwelt on other troubles which were purely mental phenomena—by which he did not imply that the sufferers were malingerers—and in the same group he placed other common causes of absenteeism, such as gastritis, neuritis or influenzal debility, with the reservation that cases of physical illness did occur under those designations.

Many of the other papers read to the congress had an interest from the medical point of view, including one by DR. STELLA CHURCHILL, on a critical examination of child welfare schemes, one by SIR JOHN ROBERTSON, on the slum problem, and one by COLONEL L. W. HARRISON on venereal diseases in the mercantile marine. In addition, there were many papers on sanitary engineering and inspection, veterinary science, and the hygiene of food.

THE SIMON REPORT AND THE MEDICAL SERVICES OF INDIA

The publication of volume II of the Simon Commission's report briefly referred to in our last issue, makes it possible to consider the probable effect on the medical services of India in the event of the adoption of the Commissioners' unanimous recommendations on this subject. In doing so however we must not be thought to forget that the problem of the Indian Medical Service is part of a far wider whole and that its satisfactory solution is contingent upon the form and spirit of the settlement towards which the recommendations of the Simon Commission important as they are constitute but a preliminary step. We were in danger of forgetting perusal of the 700 pages of the two volumes of the report which devotes a few paragraphs only to medical services would correct the tendency. Further we believe that the medical needs of the people of India as of other countries can best be met in the long run by the development of a strong independent medical profession contributing its due quota to every branch of medicine including the public services. If therefore we emphasize the importance of recommendations designed primarily to maintaining or enhancing the attractions of the Indian Medical Service for British recruits it is because in common with the Lee Commission and the Simon Commission we regard the I.M.S. as a key service in more than one sense and the maintenance of a highly qualified European element in that service for the present at least as vital to the end which all parties should have in view. We agree with the statements in the first volume of the report that failure in recruitment of the Indian Medical Service would be a serious matter for India and that the public health of India would pay a heavy price for any failure to continue to recruit the best type of research worker with the exceptional standards and traditions of the Indian Medical Service who cannot be obtained provincially. And we look to the members of that service Indian and European to supply in the not too distant future the need in all but the best hospitals for raising the standards of medical treatment with regard to which the Commissioners state that nothing impressed them more in their journeys through India. As the Army in India will be placed directly under the Governor General and the Commander in Chief, independently of the Central Legislature both the R.A.M.C. officers and the military branch of the I.M.S. should be adequately safeguarded under the new constitution. The civil side of the Indian Medical Service however still forms its main attraction to recruits for in spite of the considerable reduction during the past decade in the number of civil posts reserved for the I.M.S., those remaining afford on the average greater scope than formerly for well qualified keen officers and now that the professional opportunities on the military side have been greatly enhanced through the provision of good equipment of the hospitals and specialist appointments under the station hospital system it is at least as easy as in former times for suitably qualified I.M.S. officers to obtain attractive civil appointments. The extracts from the first volume of the report which were published on June 21st in this *Journal* sufficed to show that the Commissioners regard the maintenance of the attractions of the civil side of the medical service as essential to the welfare of India.

The striking tribute paid to the work of the Indian Medical Service in the first volume has naturally led the Simon Commission to the important conclusion that the present position, which resulted from the report of the Lee Commission should be maintained intact to allow of the supply of an adequate reserve of European officers for military purposes and to implement the pledge of the Government of India to provide European medical attendance for the officers of other services and their families without which the Commissioners rightly judge that the recruitment of Europeans in all departments so essential to the progress of India would fail. Their main recommendation in paragraph 333 of volume II under the heading Medical Treatment for European Officers therefore reads:

> European officers of the services lay great stress on the continued provision for themselves and their families of medical treatment by European doctors. We regard this as essential: no change should be made in the present Devolution Rule 12 which gives the Secretary of State in Council power to prescribe the number of Indian Medical Service officers to be employed in the provinces and the appointments and conditions upon which they shall be employed, and no effort should be spared to secure an adequate number of European recruits for the Indian Medical Service to implement this fundamental obligation. Moreover in the next paragraph on recruitment for the All India services (which of course include the I.M.S.) we state: It is certain that the European recruits of the capacity and character required can only be obtained on terms which give them subject to the exception mentioned below the same rights privileges and safeguards as we have recommended for the present members of the services. The exception is the unlimited right of early retirement on proportionate pension which is, however qualified by powers granted to the Secretary of State for India to safeguard all officers in this respect. This exception, moreover scarcely applies to officers of the I.M.S., who already possess the right to retire on gratuities after six and twelve years service, and who obtain yearly increments of pension from seventeen years service onwards.

Speedy adoption of the unanimous recommendations of the Commission should therefore suffice to safeguard the position attained by the Indian Medical Service under the reorganization scheme of 1928 and the further concessions granted in 1929 through the good offices of the British Medical Association on the strength of which a very fair recruitment has been obtained for the service during the last two years and to restore confidence in the future of the service. Meanwhile we fear that the inevitable interval of uncertainty must tend to handicap recruitment at a time when there is a good deal of leeway to be made up owing to the practical cessation of recruiting for several years before the reorganization scheme was sanctioned. Such uncertainty is however unavoidable in the circumstances and we may hope that the unanimous recommendations of the Commission in respect to the medical services will be confirmed by the Secretary of State for India with the least possible delay in some such authoritative announcement as the Commissioners themselves seem to contemplate in the statement on page 293 of volume II. We presume that as soon as

possible after the new constitution is settled a full explanation of the changes involved and their implications for the services will be made public, and that every possible step will be taken to ensure that prospective candidates are fully informed of the conditions under which they will serve."

HEPATITIS IN BILIARY DISEASE

IN an article recently published in this *Journal* Mr E R Flint[1] discussed the difficult question of the association of inflammatory changes in the liver (hepatitis) with disease of the biliary tract This is a problem which greatly interests the physician, but it is the surgeon who has the best opportunities of investigating the data Animal experiments, which must of necessity deal with comparatively acute conditions, are of little assistance since the associated changes in the liver and biliary tract are of a chronic type requiring much time for their development Evarts Graham, the discoverer of the well known method of cholecystography, was one of the first to bring the problem before us, in his paper entitled "Hepatitis, a constant accompaniment of cholecystitis"[2] His views are further elaborated in his textbook[3] published in association with his colleagues Cole, Copher, and Moore Graham propounded the question of how the hepatitis may arise Which is the primary lesion—hepatitis due to microbic infection followed by cholangitis and cholecystitis, or primary infection of the biliary tract with subsequent hepatitis resulting from lymphatic absorption? Following Graham's work, the subject has attracted the attention of other surgeons, such as Judd[4] and Moynihan[5] It has also become recognized that the cystic lymphatic gland is infected with micro organisms very early in gall bladder disease (Wilkie and others), and this has been taken as evidence in favour of primary biliary infection with secondary lymphatic spread to the liver In reality the cystic gland involvement only proves lymphatic absorption, but does not disprove in any way the view held by some that the primary lesion is hepatic, the gall-bladder infection secondary, and the cystic gland infection tertiary

An important contribution to the subject, wider in its scope than most of the papers referred to, is the book of the Beaumont Foundation Lectures, published by Heyd, Killian, and MacNeal in 1924[6] Their work takes into consideration the effects of chronic infective abdominal disease in an area outside the biliary tract—namely, the appendix The inquiry might well be extended in future by the surgeons to the effects of chronic infections of other organs draining blood into the portal system—for example, the pancreas, the spleen, and the large and small intestine Heyd, Killian, and MacNeal examined in a variety of ways the appendix, gall-bladder, and portions of liver removed at the same operation in a series of patients Hepatitis they found to be common enough when the appendix alone was diseased, due presumably to organisms or toxins spreading directly into the portal blood They noted, however, that the hepatitis of chronic appendicitis involved only the superficial layers of the liver, just below Glisson's capsule Disease of the biliary tract, in their experience, led to a much more generalized hepatitis throughout the liver tissue, extending far away from the neighbourhood of the gall bladder, and they were disposed to favour the view of continued lymphatic absorption from the gall bladder as the cause of the hepatitis Flint has taken up the subject afresh, and has carefully studied thirty-four cases His results are particularly interesting in that he has applied, in addition to the usual bacteriological and histological methods of investigation, two tests of hepatic function—the van den Bergh reaction and the lactulose tolerance test—to his cases It is in a way unfortunate, in view of the observations by Heyd, Killian, and MacNeal on the hepatitis associated with chronic appendicitis, that Flint has used as "controls" patients with appendicitis and gastric, duodenal, and jejunal ulcer, all lesions draining the portal venous bed

It is much to be desired that Flint and others will continue to investigate this problem, for it concerns what may prove to be one of the most important causes of partial hepatic insufficiency, and of permanent ill health from interference with the function of the principal "laboratory" in the human body

STERILIZATION OF THE UNFIT

SOME months ago the Central Association for Mental Welfare asked the Government to appoint a Royal Commission "to make full inquiries into the causation of mental deficiency, into its relationship to other abnormal conditions and social problems, and into any measures, including both segregation and sterilization, by which it might be prevented" The Council of the British Medical Association endorsed this suggestion with the proviso that any suitable body other than a Royal Commission might be accepted for the purpose of the inquiry The Minister of Health, however, expressed the opinion that the proposal was not yet opportune, but said that the question might well be reopened at some more favourable time It is probable that this will be done in the not very distant future Meanwhile, as is proper and desirable, the discussion on these matters continues, and a useful contribution to this discussion is made by Dr Frank A Gill, medical superintendent of the Calderstones Institution for Mental Defectives, in his report to the Lancashire Asylums Board, under whose control that institution is conducted The essential thing in any controversy about the effect of sterilization is to distinguish carefully between the various purposes for which it may be advocated That it may be an appropriate measure in individual cases for personal or family reasons is scarcely in dispute as regards its medical or scientific aspects This being admitted, the questions at issue are (1) whether it is of sufficient value to be adopted as a routine measure in selected cases of mental deficiency and of recurrent insanity so that a larger number of such cases may be properly released from institutional care, and (2) whether it is of any practical value as a eugenic measure for the betterment of the race It is one of the merits of Dr Gill's report that he distinguishes between these two questions, though even here there is occasional confusion He admits, even emphasizes, the futility of sterilization for the latter purpose "The fallacy of this claim of wholesale sterilization lies in the fact—and it is a fact—that the great majority of certifiable defectives are not the progeny of mentally defective parents, but of apparently normal or subnormal yet more or less self-supporting citizens, whom no sterilization laws could touch or seek to touch The majority of victims of mental infirmity come of families who are the subject of some mental instability, whose germ cells are in some way faulty, and who may only be carriers of defect without themselves exhibiting any trace If every certifiable mental defective had been sterilized twenty or thirty

years ago it would have made little appreciable difference to the number of defectives existing to-day" As we have previously said on more than one occasion, it is clear that in order to produce any practical effect as a eugenic measure sterilization would have to be applied to a proportion of the population which would certainly not be less than one-tenth of the whole While, however, Dr Gill concludes that "a policy of wholesale sterilization of the mentally unfit is neither necessary nor desirable," he maintains that it is desirable in the recurrent insane, in certifiable women who become pregnant or are immoral, and in selected cases before release from institutions There is undoubtedly a strong case for this contention, though the extent to which institutional provision would be relieved by such measures is open to grave doubt If future discussion could be kept on these lines and directed to this thesis much would be gained This will be difficult of attainment, for Dr Gill certainly underrates the extent to which public opinion, even intelligent public opinion, is misdirected in this matter—even by certain persons and societies who might be expected to know better Dr Gill mentions the argument brought forward by opponents of sterilization "that public opinion may seize on sterilization as a cheap and economic remedy for dealing with the problem of the unfit, and so cease to make adequate provision in the way of institutions and hospitals," but is satisfied that if the problem is properly understood these arguments may be dismissed as futile But is it futile to point out the dangerous situation that may arise if the public accepts the view that sterilization can be an effective substitute for segregation, and that it can be adopted as a measure by which mental defect can be racially eradicated cheaply and relatively quickly? It is important to bear in mind that the campaign in favour of sterilization is at present being mainly carried on by these arguments, the fallacies of which have been exposed over and over again

THE FOOT AND THE SHOE.

In an article with this heading in our issue of October 12th, 1929 (p 678), we commented not very hopefully on the difficulty of persuading wearers of shoes to abandon harmful fashions in their own interests In glancing at the history of footgear we dwelt chiefly on the form of the shoe, and on the pointed toes and high heels preferred by most women We scarcely touched on the materials used by shoemakers Nevertheless, the substances used in making all parts of the shoe are not without their importance This aspect of the matter has lately been considered by the Incorporated National Federation of Boot Trades' Associations, Limited, the general secretary of which has sent us some account of an analysis of the answers to a questionary which was recently sent to two hundred medical officers of health Anything which affects the health of the individual must in the long run collectively affect the public health, so that from a general point of view no doubt the federation was well advised to consult medical officers of health We question however, whether those officials see as much of the evil effects of improper footgear as do general practitioners and orthopaedic surgeons We take it that the federation does not aspire to add to the sanitary duties of the Ministry of Health the regulation of the people's boots and shoes Legislation of that kind has been carried out in other days and in various countries, but such sumptuary laws have generally failed to attain their object King Charles V of France attempted to regulate the length of the pointed "poulaine" shoe according to the social status of its wearer, but the fashion only ceased when the swing of the pendulum brought in the broad toed Tudor shoe which in its turn soon went out of fashion We do not envy the task of the medical officer of health and his inspectors who might be charged with the duty of dictating to the women of the present or a future day what kind of shoes they should wear, or what materials the shoes should be made of The questionary of the federation has not brought to light any very startling or new facts Somewhat sweeping statements are made about the extent to which the general health is affected by footwear The recommendations that "boot and shoe makers should scrap present-day lasts in order to do away with shoes of unnatural shape and pointed toes," and that "ultra-high heels should go," seem to us counsels of perfection, unless the requisite could be enforced throughout the world If British bootmakers refused to supply "fashionable" shoes the imports from the Continent and America would become enormous The "perfect" boot or shoe, according to this report, would lessen "the ill effects on national health of rheumatism, chest troubles, heart disease common colds foot deformities, fallen arches and flat feet" As to the three last there can be little doubt but the influence of shoes on the other disorders is more problematical, although we are told that "55 per cent of the doctors said that these ailments and many others are due to the wearing of defective and unsuitable footwear" One medical officer of health is credited with the suggestion that "models or casts of feet from Greek statues, such as the Venus de Milo, giving size and shape would encourage less foolish women to buy shoes of correct shape and size" This officer is evidently an optimist As to materials, the federation and the doctors are agreed that "there's nothing like leather" Such statements as the above in the nature of things, are only the outcome of general impressions, lacking any precise statistical foundation The medical officers of health were on firmer ground in denouncing high heels and pointed toes, but neither the questioned nor their questioners made any practical suggestion as to how the female public is to be persuaded to reform its ways in the choice of its footwear Appeals to reason and common sense have hitherto failed and are likely to continue to fail, on deaf ears Nothing less than a change of heart could effect the necessary reform and to bring that about a sutorial Wesley is urgently needed who should be the apostle of broad toes and should finally extirpate the digitigrade heresy

THE ROYAL SOCIETY CONVERSAZIONE

Those who attend the conversaziones of the Royal Society have learned not to be surprised at finding side by side in the same room—as they did last week—corals from the sea bottom, photographs of a new planet, relics of prehistoric man, and a new device in gramophone recording equipment whereby at intervals the scientific atmosphere vibrated to the latest music-hall tunes, or, again such exhibits shown in contiguity, as specimens of ancient art excavated at Ur of the Chaldees, a new x-ray tube by Mr Culbert Andrews, said to be the only tube of British manufacture which incorporates its own protection (a protection equivalent to about 3½ mm of lead) and a display from the Natural History Museum illustrating parasitism in the case of certain Nigerian frogs whose eyes and lacrimal glands harbour clusters of oligochaete worms Among the many things that caught the eye was an electrical device for showing normal and abnormal heart rhythm with the aid of relaxation oscillations produced by neon tubes This model, the work of Dr van der Pol and shown by Philips Lamps Ltd, consisted of three neon resistance coupled valves representing sinus, auricles and ventricles and by means of connections of coupling (representing the bundle of His) normal rhythm or partial or complete heart-block could be obtained with electro-cardiograms of the various arrangements The National Institute of Medical Research had an exhibit illustrating a hitherto undescribed virus disease in mice The disease is recognized by the occurrence of [illegible] ing, usually on one hind leg followed by gangrene and

separation of the affected portion of the limb This has been found to be due to a virus which under certain conditions, constantly passes through filters which hold back bacteria Dr R Robison of the Lister Institute, with Dr H B Bell showed specimens indicating the development *in vitro* of the mandibular skeletal tissue and limb periosteum of the embryonic fowl, and Mr C H Waddington experiments (also shown by Dr Canti on his film) on the living embryo which had been removed from the chicken's egg soon after it was laid, and allowed to continue its differentiation *in vitro* From the Strangeways Research Laboratory Cambridge, again came an exhibit of the effects of x rays on tissues growing *in vitro* and *in vivo* The cast of the Peking skull (*Sinanthropus pekinensis*) shown by Professor G Elliot Smith claimed the largest share of attention This brain case was found in December last by the Geological Survey of China at a spot some forty miles from the Chinese capital It was described by Professor Elliot Smith as probably the most significant cranium of early man ever discovered It comes from a geographical area which hitherto has revealed no trace of ancient man The skull shows features some of which were unknown hitherto except in *Pithecanthropus*, and others only in the Piltdown skull The *Sinanthropus* is a link between these two types, and brings into correlation what hitherto have been the irreconcilable contrasts which separate them one from the other The value of the skull, according to Professor Elliot Smith is that it gives cohesion to the knowledge of the earliest human remains and makes it possible to conceive the qualities of the common ancestor of all three types—in other words the nature of the, as yet undiscovered Pliocene man The Peking skull was found not in gravels, but in the floor of a cave where the primitive man actually lived, and was in an uncrushed state and in more complete form than previous discoveries thus giving a more convincing idea of the shape of the primitive brain case and more confidence in the essential accuracy of the reconstruction of the Piltdown skull by Dr Smith Woodward in 1912 The temporal bone of the Peking skull presents features of quite exceptional interest and importance It is very much more primitive than that of the Piltdown skull, and its general morphology presents a striking resemblance to the condition of the adult anthropoid apes Professor Elliot Smith also showed a cast of the first lower molar tooth found in October, 1927 at the same place, the Lower Pleistocene cave-deposit as that in which the skull was subsequently discovered On the evidence of this tooth Professor Davidson Black postulated a new genus and species, *Sinanthropus pekinensis*, the justification for the new genus being based partly upon the unique morphological characters of the tooth, the fact that its proportions differed from all known human and simian teeth and occupied a position intermediate between them and also the remote antiquity of the tooth indicated by the geological evidence, which assigned it to the Lower Pleistocene The discovery of the tooth was followed a year later by the discovery of fragments of two jaws and later still six months ago, of the brain case

THE ORGANIZATION OF RHEUMATISM CLINICS

Now that several new clinics for the prevention and treatment of rheumatic diseases are beginning their attack on these crippling disorders, it is well to consider the best way in which the work can be done Dr R Fortescue Fox, in a recent number of the *Acta Rheumatologica*,[1] points out that the great enterprise now being undertaken is largely experimental The difficulty is, he says, that the workers are using unfamiliar tools for a job that they do not understand, and out of his forty years' experience in this subject he suggests certain lines of investigation for the rheumatic cases The important subject of causation can be studied particularly well at the new clinics, where early and chronic cases will be under continuous observation In Dr Fox's opinion there are four factors which should especially be investigated external conditions, constitutional anomaly, infection, and the skin Under the first heading come geographical and climatic incidence, housing and occupation In addition to records collected by medical officers of the rheumatism clinics it is suggested that some of the national societies for the study of rheumatism should organize inquiries on a wide scale and furnish returns The question of the constitutional anomaly is especially one for the medical officer at a clinic who is in a good position to investigate the difficult subjects of "hereditary predisposition" or "familial tendency" As Dr Fox remarks, such observations are difficult to record in a precise and statistical form, yet the longer the experience of the physician the more familiar he becomes with the importance of constitutional factors With regard to infection, the problem which calls for elucidation is whether organisms found in the search for possible foci are really operative or inoperative as infective agents, and, further, how to deal with organisms within the body The fourth factor, the skin, in Dr Fox's opinion, stands more in need of study in its relation to organs and its functional condition in chronic disease than any other medical topic Some suggested lines of inquiry for the student of rheumatism include systematic mapping out of skin temperatures *both of exposed and of covered parts* Cold areas of skin are very common in chronic diseases, and what is needed is accurate observation by rapidly acting surface thermometers The degree to which perspiration is in abeyance temporarily or permanently, also requires investigation in rheumatic disorders, and further details are needed about the peripheral circulation Dr Fox finally urges that all statistical records by national societies should be expressed in the terms proposed for provisional use by the British Ministry of Health He deplores the current tendency to premature definition which may easily confuse the issue As a temporary expedient he believes that classification on a basis of age-groups is the best to be followed Alternatively a therapeutic classification offers interesting possibilities for if one hundred cases of arthritis were submitted to the same treatment they could be usefully classified according to the reactions manifested "Only the physician at the bath side can properly recognize and interpret the complex physiological reactions to treatment" Dr Fox's forty years' experience at the bath side warrant a close study of all his suggestions

[1] *Acta Rheumatologica* No 5

THE PRICE OF RADIUM

In his recent presidential address to the Institution of Mining and Metallurgy, Professor J G Lawn referred to radium as affording the most striking example of high price in the whole history of metals It is now worth approximately £14,500 a gram There are 31·1 grams in the ounce troy so that the value of radium is more than a hundred thousand times its weight in gold, and a ton at this price represents nearly twice the national debt Professor Lawn added that radium had such valuable properties that in spite of its price there was a trade in it on a very small scale, the sales in 1928 amounting to some forty grams The only consolation to be derived from Professor Lawn's figures is that the price, high as it is, is little more than half what it was during the war In pre-war times the price of radium, obtained from Austria, was anything from £16,000 to £32 000 a gram Then, for several years, it was produced on a fairly large scale in the United States from carnotite During the war the price reached £25,000, and occasionally £27,000, afterwards becoming stabilized at £24,000, except for occasional sales of large quantities at a lower figure Later, with the discovery of new sources of high-grade radium ore in the

Belgian Congo, the cost of production was lowered to a price with which American carnotite could hardly compete, and the price was reduced from £24,000 to about its present level Professor Lawn stated that radium is fairly widely distributed, and most countries possess ores which carry it, but it occurs in such minute quantities that there seems little hope that it may be produced on a larger scale or at a cheaper rate than at present

THE BRETTAUER COLLECTION OF MEDALS

THE University of Vienna is in possession of a large and important collection of medical medals—"Medicina in Nummis"—presented by the well-known research scholar Dr Josef Brettauer of Trieste, who died in 1905 The collection comprises some 7,000 medals, among which there are many artistic and historical works of value, representing Renaissance, Baroque, and modern art It covers a wide field, and offers material of great interest to the student of medical history There are three main groups The first concerns physicians of all times and nations, the second epidemics (especially plague, small pox, cholera) and famines The third group comprises, in many subdivisions, *medals referring to healing gods and patrons of medicine, hospitals and welfare institutions, medical corporations* and congresses, nursing and ambulance, nearly all special branches of medicine and the medical auxiliary sciences, pharmacy and veterinary science, etc, besides amulets, tokens, and satirical medals The control of this precious collection was recently transferred to the Medal Cabinet of the Vienna Art-History Museum In accordance with the regulations of the foundation deed a small selection is exhibited to public view, while the remainder, housed in the exhibition room of the federal collection of medals, coins, and money-tokens, is open to all interested in this branch of science The publication of a scientific catalogue of the Brettauer Collection, *with photographs and* drawings of medals of special historical importance, is most desirable, but the cost of this cannot be covered altogether by a donation from the Austrian Government An appeal is therefore made on behalf of the committee by Professor Max Neuburger, president of the Institute of Medical History, and others, to all friends of science and art, and especially to medical historians and numismatists, and to medical faculties, associations, and societies, to send contributions to the office of the Rector of Vienna University A list of donors will be published in an appendix to the catalogue

MR J C GARNER.

OLD contributors to these columns, who have good reason to appreciate his worth, will regret to learn of the retirement of Mr J C Garner after more than twenty six years as head reader on the staff of the *British Medical Journal* When he entered our printing office in 1904 Mr Garner had already had long experience in the preparation of medical papers for the press, and Sir Dawson Williams laid upon him the duty, under Mr Louis Taylor's immediate supervision, of bringing the typographical practice of the *Journal* up to the highest standard To them and to their successors he has given loyal and unstinted service, counting no effort too great in the maintenance of accuracy and good form in printing, and the right use of scientific terms His work was not confined to proof correcting, but included the revision of copy Few medical writers and very few readers recognize their debt to such men, under whose expert hands a slovenly MS takes presentable shape, and a rough and undigested mass of figures and obscure symbols emerges as a clear and well-balanced table "It looks better in print than I expected," says the author, dimly aware that something has been done for him, and with this faint approval the skilled and conscientious worker in the background is usually content, his true reward being the knowledge that one more piece of work that matters has been done as it should be done In taking leave of Mr Garner we offer him the gratitude due to a good and faithful servant of the British Medical Association and its *Journal*

THE Lister Memorial Lecture before the Royal College of Surgeons of England will be delivered at the College, Lincoln's Inn Fields, W C, by Dr Harvey Cushing, professor of surgery, Harvard Medical School, on Wednesday, July 9th, at 5 p m The subject of the oration will be "Neuro-hypophysial mechanisms from a clinical standpoint"

ROYAL SOCIETY OF MEDICINE

ANNUAL GENERAL MEETING

THE annual general meeting of the Royal Society of Medicine took place on July 1st, with LORD DAWSON OF PENN in the chair

The first business was to elect officers and council for the session 1930–31 A motion by Dr PEACHEY to adjourn *the meeting for fourteen days on the ground that, as he* alleged, there had been some irregularity in regard to the suspension of the nominations in the library as required by the by-laws, was negatived, but the president promised that the procedure of nomination of officers and council should be reviewed by a committee when the new session started in October No counter nominations had been received to those set out in the notice, and accordingly the following were declared elected

President Dr T Watts Eden.
Treasurers Dr A M H. Gray and Mr W Girling Ball.
Hon Secretaries Mr E K. Martin and Dr George Riddoch
Hon Librarians Dr William Bulloch and Mr H. W Carson.
Hon Editors Dr Hugh Thursfield, and Mr J Swift Joly
Council Sir John Bland-Sutton Mr Zachary Cope Dr F R Fraser Mr Sampson Handley Dr Dorothy C Hare Sir Stanley Hewett Mr Hugh Lett Mr Warren Low, Lord Moynihan of Leeds Dr Bernard Myers Dr A. E Russell Sir S Clair Thomson Sir John Thomson Walker Dr H. Letheby Tidy and Dr G de Bec Turtle

The report of the council for the last session was submitted It stated that the roll of the Society included 39 Honorary Fellows, 4,047 Fellows, 193 corresponding members, 378 members of Sections, and 64 associates, the use of the Society's house by the Fellows was now greater than ever, and the time was approaching when an additional meeting room would be needed, which it was hoped to secure by building a top story The accounts revealed a total income of £21,125 and a total expenditure of £20,025 Through the kind offices of the president, the Society received during the year a sum of £2 800 from Mr Stanley Baldwin, allocated at the time he was Prime Minister, from a fund placed at his disposal by Lord Beaverbrook This gift is the subject of a special trust which will be administered by a specially appointed committee The income is to be used for purposes for which the general funds of the Society would not ordinarily be available The Society has also received from Lady Singer £500 in memory of the late Sir David Ferrier

SIR JOHN THOMSON-WALKER, in moving a vote of thanks to Lord Dawson of Penn, said that it had been a wonder to him how, with so many calls on his time he had found energy to take the interest which he had done in the Society Lord Dawson had shown endless tact, great firmness, and an anxiety to see the Society make progress

LORD DAWSON, in response, said that to have been president was a great privilege and the privilege had been rendered a delight by the consistent support and encouragement he had received from his colleagues on the council and the executive officers No man could a pire to a higher honour than to be president of the Society, which gathered together a greater number of co-ordinated activities than any other institution in the country He handed on his office to a colleague (Dr W [illegible]) who had tinguished the world over in the [illegible] belonged and known for his [illegible] counsel

RESEARCH IN ANIMAL GENETICS*

BY

SIR EDWARD SHARPEY-SCHAFER LL.D., F.R.S.E.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF EDINBURGH

The Animal Breeding Research Department at Edinburgh was established some ten years back to investigate the principles which should govern the breeding of animals employed in agriculture. The first step was to select someone to carry out and direct research on the subject—no easy task, and our choice was fortunately fixed on the present director, Professor F. A. E. Crew, who had already made a name for himself as an authority on genetics. As a result the department has already become an unqualified success, not only in the objective sense, as manifested by the buildings we are assembled to inaugurate, but much more in the personnel which the director has been able to gather round him, and in the work they have already effected.

Research Problems in Animal Breeding

It might be thought that as the department was established for the encouragement of agriculture, and that the avowed object was to improve the breeds of animals used for agricultural purposes, the choice of a director would have fallen upon an agriculturist accustomed to the breeding of stock, who would surely have been best able to judge what results were required and how these could be arrived at. Those who hold this opinion would consider that in appointing a purely scientific man, with little or no experience in the breeding of farm animals, the committee made an initial mistake. But the breeding of animals, like all applied sciences, must be founded upon a basis of pure science. Moreover, it is essential that it should, like every other branch of science, be based upon experiment. Now it would be possible for experiments in breeding to be carried out on ordinary farm animals with a certain amount of success. But the length of time one has to wait for the result of experiment in animals which have a gestation period of many months greatly limits the number of experiments which can be made, and renders the progress of research very slow, moreover, from the interbreeding which has been going on for long periods in most domestic animals, the results may be uncertain. As a concrete example we may cite the Penrcuik experiments on telegony by Professor Cossar Ewart. By telegony is meant the influence exercised upon the mother by the foetus *in utero*. Not long ago every breeder in the country believed that if a female of pure breed was crossed by a male of the same species but of another breed or of no breed at all, the resulting progeny would so influence the maternal organism that this particular female would never again—even if crossed by a male of exactly the same breed—produce pure progeny, that, for example, a mare of the purest blood would be permanently ruined for stud purposes if she were in foal to a stallion which had no pedigree behind him. The circumstance was thought to be proved by the observation of Lord Morton, communicated to the Royal Society in 1820, that a mare which had produced a hybrid foal to a quagga—a species of zebra—and was afterwards crossed by an Arabian horse, happened to produce a foal which exhibited distinct stripes; these stripes were supposed to have been caused by an influence exercised upon the mother by the hybrid foal in utero. The [illegible] that several heirs of telegony was, however, definitely [illegible] ment of [illegible] quest[illegible] so far as the equidae are concerned, by Professor Ewart, settled in the negative, who crossed mares, first with zebra stallions, producing hybrids which showed distinct stripes, and subsequently with ordinary horse stallions. The progeny of the second crossing never showed signs of the zebra influence, although faint stripes were sometimes visible in the foals, but not more than [illegible] foals in which stripings are sometimes noticed [illegible] induction that the horse had at one time a striped ancestor. These experiments took years to bring to a conclusion and cost hundreds of pounds, but similar experimental results can be obtained in a comparatively short time by selecting small animals with short periods of gestation. Nor is it necessary to employ mammals alone for such experiments. For many purposes birds are even better adapted. And as the experiments of T. H. Morgan and others have shown, the laws which govern heredity and the morphological conditions which accompany and determine the transmission of bodily characters may be even more advantageously studied in certain invertebrate types, such as drosophila. Nor are these laws essentially different in the animal and vegetable kingdoms. The law of heredity discovered by Mendel was the result of experiments upon crossing varieties of sweet peas. And of late years a vast amount of work of the same kind has been carried out on different kinds of plants, which in some particulars lend themselves even better than animals to the elucidation of the principles governing heredity. It may be added that these experiments illustrate the fallacy of the saying "Natura non facit saltus." Rather would it seem that in nature frequently does work by leaps, and that intermittence is often the rule, continuousness the exception.

Application of Genetics to Man

Just as the principles of genetics are applicable to plants as well as to animals, can they equally well be applied to man. I suppose that nowadays all educated persons admit that mankind is only the highest type of animal, and therefore that all laws which regulate the lives of animals, including those which determine heredity, apply equally to him. If we were able to use the knowledge acquired in breeding animals for the improvement of our own race, we might eventually succeed in eliminating much that tends to keep the race physically and mentally far lower than is desirable. At present all that we can do is to educate the individual. Much, no doubt, can be effected in this way, but education is useless unless there is an inherent power to be educated.

But civilization has not progressed enough to permit even an endeavour to promote amelioration of the race by breeding from the highest types. All that seems possible is the prevention or breeding from the lowest types. Unfortunately there is a grave risk of an inferior type becoming established, for it happens that the reproductive faculties are better developed in mentally inferior than in superior types. It is the object of eugenics to combat this downward tendency of the race, though how this predominance of the unfit can be prevented is a difficult and controversial problem. It is, however, a problem which urgently demands solution, since the future welfare of the human race hinges upon it.

Study of Sex Hormones

The study of animal genetics depends in the main upon physiology, probably that is the chief reason why I have been asked here to-day. Particularly it concerns the physiology of the sex cells and the organs in which these are produced. The sex cells are not the only elements produced by the gonads. Both in the male and in the female there are other cells which exert a profound influence upon the organism. This influence is the chief cause of what may be termed "maleness" or "femaleness," these qualities showing themselves not only in the physical features characteristic of the respective sexes but also in the psychical attitudes which are equally sex-distinctive. One of the most interesting advances in the science of genetics has been to prove that these so-called secondary sex characters—whether corporeal or psychical—are dependent, not on the sex cells themselves, but on the other cells just mentioned. These other cells, however, do not exert their influence directly, or even through the nervous system, but they manufacture specific chemical substances which are passed into the blood and circulating throughout the organism, are brought into contact with every cell in the body. These chemical substances belong to the class known as autacoids, they either stimulate activity (hormones) or restrain activity (chalones). They are of relatively simple composition, some have been obtained in a crystalline form. The

* From an address at the opening of the Department of Animal Genetics, University of Edinburgh, on June 30th, 1930.

administration of extract of the gonads to immature animals (or to animals deprived of their gonad) is followed by the development of the special secondary sex features, both physical and psychical, characteristic of the sex from which the extract has been obtained. The substances in question are zoologically non-specific, in other words, it matters not how different the species of animal from which they have been obtained, the same results are yielded as if they had been derived from an animal of the same species as that to which they are administered. From this is it clear that genetics involves the study not merely of the structure and functions of the sex organs but also that of their chemical products: this branch of the subject is increasing in importance every day.

Genetics has, however, not merely to do with the activities of the sex organs themselves, it is concerned also with the effect upon them of the nervous system and of internal secretions other than those produced by the gonads themselves. It has been recognized from the earliest times that the nervous system exerts a profound influence upon the sex organs and is in its turn profoundly influenced by them. But it is a matter of comparatively recent observation that there are influences acting from outside upon the sex organs which are not nervous. We term such influences "humoral," indicating thereby that they are conveyed to the sex organs by the blood. In other words, they belong to the class of autacoids to which we have been alluding. Those of which I am about to speak however, are not to be confused with the autacoids producing secondary sex characters, though some are also manufactured in the gonads. For example, the ovary manufactures hormones which cause ripening and discharge of ova and changes in the uterus which are not responsible for the development of the sex characters. That autacoids related to the reproductive function should be formed in the sex organs themselves is not an altogether unexpected result: but the remarkable observation has lately been made that the pituitary body produces autacoids which are carried by the blood to the ovaries, and excite the internal secretion of those organs so as to cause a ripening and discharge of ova and the accompanying changes in the uterus even in immature animals.

The story of the pituitary body is a real romance—with the distinction that there is nothing of fiction about it. Long known to be present in all vertebrates, its functions, like those of most of the internally secreting organs, were until recently unrecognized. But the clinical observation of cases in which the gland had undergone enlargement and in which there was overgrowth of the skeleton and of the body generally suggested that it might yield an internal secretion which is concerned with growth. This could be tested by experiments on young animals—experiments involving on the one hand administration of pituitary substance, and on the other suppression of the secretion by removal of the gland or of the larger anterior part which is recognized as the part concerned with growth. If it is yielded to the blood in undue proportion growth may be so much stimulated that a giant is produced. On the other hand, if from any cause this internal secretion of the pituitary body is not passed into the blood or not in sufficient amount, growth will be arrested. Administration of this part of the pituitary has been found to increase the animals' size above normal, whereas destruction of the same part arrests growth and produces dwarfs. Whether there is also a material in the internal secretion of this or some other gland which actively prevents growth is not determined, but is not altogether improbable.

The internal secretion of the pituitary not only influences the general growth of the body, but especially the growth and maturation of the generative organs. A young animal deprived of its pituitary not only ceases to grow but remains infantile, its sex organs do not mature. On the other hand, the administration of anterior pituitary stimulates general growth, and especially the development and maturation of the gonads causing an immature animal rapidly to mature sexually. In a young female pituitary will cause the production of ripe ova, this it does by acting as a stimulus to the internal secretion of the ovary itself, causing that organ to produce those substances which in adult animals effect maturation of ova and their fixation in the uterus.

Direct evidence that the pituitary substances which thus act on the ovary are poured into the blood can be obtained. They happen to be present in larger amount during pregnancy than at other times. Their effect can then be got simply by injecting a few drops of blood from a pregnant female into a young female mouse. A short time after such injection the mouse's ovaries, which were very small and immature, become enlarged and exhibit unmistakable signs of maturation, the Graafian follicles becoming large and haemorrhagic like those which in mature animals are ready to discharge their ova. Even more remarkable is the fact that these substances do not remain in the blood of the pregnant female, but are got rid of by the kidneys being passed into the urine, in which they occur in considerable amount. So that, instead of blood a drop or two of urine injected under the skin of an immature female mouse will easily furnish unmistakable evidence of the existence of pregnancy, even at so early a stage that none of the ordinary signs of that condition is exhibited. This is known as the Zondek-Aschheim test for pregnancy.

Animal Experiment in Medicine.

Everyone can appreciate how important it may be to make an early diagnosis of pregnancy. Yet by the laws of this country, no medical man is permitted to carry out the Zondek-Aschheim test unless he has a licence to practise vivisection, and even then he may only do so in a place registered under the Act. He must also obtain from the Home Secretary a special certificate permitting him to keep a mouse alive for the few days necessary to enable the result of the experiment to be observed. It happens that the laboratory, which we are now enabled to declare open is at present the only one in the country which undertakes this duty, though strictly speaking the resources of an establishment intended to be devoted to research pure and simple should not be diverted to a routine method of diagnosis which might as well be done anywhere else and by any medical man who has been instructed in the method.

It is even still more extraordinary that hospitals should debar themselves from making such necessary observations. This applies not only to the diagnosis of pregnancy but even more to that of diseases the rapid and efficient diagnosis of which depends upon experiments involving the inoculation of animals. But even when the hospital possesses a well-equipped laboratory experiments upon living animals whether for diagnostic purposes or not are usually barred by the authorities responsible for the administration of the hospital. Samples of blood, or morbid growth, or urine must be sent away to be tested on animals: no such experiments are allowed under the same roof as the patient whose condition has to be diagnosed. The reason for such a state of affairs is only too apparent, it is due to apprehension that the subscriptions of anti-vivisectionists will cease to be forthcoming and that the revenue of the hospital will suffer. On this account hospital authorities will not permit any part of the premises to be registered under the Act, or any operations or even inoculations for diagnostic purposes, to be made on living animals. A mouse may not even receive a hypodermic injection although the operation on the mouse may lead to the cure of the man. This is not only wrong in principle it is not honest, and honesty is always the best policy. A hospital is provided for the treatment of disease for which rapid and accurate diagnosis is of major importance. Considerations of finance or misapplied sentiment should never be allowed to override this fundamental principle. The time is long past when a surgeon was bold enough to declare that no experiments on animals had ever contributed to his knowledge or influenced his surgical procedure: all declaration merely showed his ignorance of the history of medicine and of physiology on which all medicine is based. The science of medicine the operation of surgery the use of drugs, the application of preventive and curative measures to the health of the community as a whole and in with animal experimentation. Even if the State is opposed to experimen on animals it cannot choose but must permit for the to be carried on

assuming office how essential such experiments are for the progress of medical knowledge and for the public health The anti-vivisection societies have, and can have, no real influence their propaganda will never prevent a sick person from calling on the services of a doctor whose knowledge is founded on vivisection

It must be understood that all the work of this and kindred institutions is based upon vivisection Literally the word means the dissection of living animals, and therefore every surgical operation is a vivisection But technically and legally it means any experiment on a lower animal of any kind, whether by operation, or by injection, or merely by feeding This definition of vivisection is not mine, it is that given by the Act of Parliament regulating the practice No one can make any sort of experiment, whether it is painful or not, upon a vertebrate animal —even upon a fish or tadpole—without a licence from the Home Secretary That is to say, provided the experiment is made to advance knowledge and not for sport No farmer may test the effect upon his stock of a novel food without a licence, if he conducts such a test he makes an experiment for the purpose of advancing knowledge, and, if his animals suffer from the change of diet, he renders himself liable to prosecution Thousands of experiments on animals are recorded every year and reported to Parliament by the inspectors under the Vivisection Act At least 99 per cent involve no operation, they consist merely of feeding, or at the most of hypodermic injection By far the greater number are done in connexion with, and by the direction of, the Public Health Services of the country All operations which involve incision are performed, like surgical operations, under profound anaesthesia, and if an animal is kept alive after operation it is treated in exactly the same way as a hospital patient, the only difference being that if the animal appears to be suffering pain it is killed painlessly by chloroform We who experiment upon animals have every regard for the sufferings of animals, but we have a greater regard for the sufferings of humanity Very appropriate, therefore, are the words which Professor Crew has caused to be carved at the entrance of this institute, which I now formally declare to be opened: "To the advancement of science and to the service of mankind this building is dedicated"

WATER POLLUTION.

ADVISORY COMMITTEE'S REPORT

THE second report[1] of the Joint Advisory Committee on River Pollution, under the chairmanship of Mr Herbert Brooks, with Dr H. Maclean Wilson as medical member, deals with the reception of liquids from industrial and manufacturing processes into the sewers of local sanitary authorities The growing tendency of factories to settle on river banks conflicts with the necessity of conserving all sources of water supply and with efforts to safeguard the amenities of life No drastic measures are advocated by the committee Easily adopted changes are considered advisable at present, and suggestions are outlined for new legislation

General Legislation Regarding Trade Effluents

The position of local authority and trader in regard to the disposal of trade effluents is regulated to some degree by the Public Health Act of 1875 and by the Rivers Pollution Prevention Act of 1876 The first required sanitary authorities to provide sewers to drain their districts effectively, and permitted any occupier of premises within the area to allow his drains to empty into those sewers The second enacted that the sanitary authorities should afford facilities to manufacturers within the district to conduct to sewers the liquids resulting from their trade processes No authority, however, was compelled to admit fluids potent enough to injure the sewers or to cause any sanitary trouble Nor was it bound to allow these facilities if its sewers were no more than adequate to the needs of the district The two Acts were vague enough to create ambiguity as to what the trader might demand and the authority refuse Legal opinion has made it apparent that the obligations of the sanitary authorities are defined by Section 7 of the Rivers Pollution Prevention Act, with the limitations already stated But these limitations are so comprehensive that they almost cancel the general obligation, and they are so imprecisely framed that their intentions have sometimes been questioned Moreover, the powers of the local authority in regard to expenditure and the fixing of conditions are uncertain, and agreements with traders willing to pay for facilities and observe regulations are inhibited by the fact that other traders may claim admission for their effluents without promising to observe the same conditions and without payment Meanwhile other Acts of Parliament—for example, the Public Health Amendment Act of 1890—help to protect the sewers from liquids that are actually or potentially dangerous to health

Trade Effluents and Local Legislation

Local legislation and practice supplement with varying success the indications of general law In some districts the position has been clarified by special legislation Many of these local Acts cope with some special difficulty rather than deal with the general principle of right of access to sewers But corporation Acts of a comprehensive kind prevail in seven districts, including Halifax, Huddersfield, Dewsbury, and Salford The codes embodied in these statutes are evidently based on the third Report of the Royal Commission on Sewage Disposal, issued in 1903 Where they are in operation, their practical effect is to supersede Section 7 of the Rivers Pollution Prevention Act, and to substitute for it a more detailed machinery to regulate the relations of local authority and trader They give the trader a definite right to discharge his effluent into the sewers, and impart to the local authority such powers and obligations of disposal as it already possesses in regard to ordinary sewage They also authorize local authorities to co-operate with each other in the exercise of certain rights and duties None of these provisions, however, affect the existing water rights of a riparian owner This system assumes that the local sanitary authority should deal with trade effluents, and it appears to operate smoothly and effectively by working through discussion between the two parties

Recommendations for New Legislation

The committee is convinced that the general law concerning trade effluents is at present too indefinite There is marked necessity for a new code, stating precisely the rights and obligations of the trader and of the local authority, [illegible] and the organs in [illegible] enough to vary in details yielded to the [illegible] are not the [illegible] of the Huddersfield so much stimulating [illegible] suggest the kind of general law required for populous cities The central recommendation of the committee is that the local authority should everywhere accept the responsibility for the disposal of trade effluents Its standard of purification will undoubtedly be higher and less expensive than in any system arranged by an individual trader A single centre, under skilled and constant supervision, will protect the river more thoroughly than the independent control exercised by those whose interests are concerned with their products, and who can hardly afford a skilled supervisor Besides, some effluents are best disposed of when diluted with domestic sewage There are effluents, of course, which may be properly debarred from entering the sewer Rivers bordered by a line of industrial works will need exceptional consideration But no objection seems cogent enough to affect the recommendation that the local sanitary authority should receive and dispose of trade effluents as simply and as completely as it deals with domestic sewage

[1] H.M. Stationery Office 6d.

The committee is of the opinion that the conditions governing the exercise of the right of access to sewers must be fixed by locally drafted regulations, qualifications of the right must vary with regional peculiarities The flexible code of regulations should be formed by agreement between the local authority and the traders, with reference of unsettled questions to the arbitration of the Minister of Health Should the traders fail to appoint representatives the local regulations will be framed by the authority alone Either party may call for modifications at any time Among the matters to be determined by the local code are the preliminary treatment and removal of substances, the regulation of flow, financial arrangements and the inspection and taking of samples

Minor provisions directly related to the chief recommendation are detailed in the report Conflicts between different interests in the river can most, the committee thinks, be solved by a little good will The new principle must be applied tactfully, and in some districts without undue haste But the committee does not approve of the suggestion that an adoptive Act would meet the case The disquieting inclination of industry to spread itself over districts not industrialized before and the absence of initiative in securing measures for the adequate protection of many rivers, make it necessary to embody the new system in general legislation In districts where the problem does not exist, the position would not be changed In larger districts the authorities would proceed at once by calling conferences of the traders If the authority remained inert for twelve months a trader could set this machinery in motion by demanding access to the sewers

Research on Water Pollution

Some idea of the practical measures that are being undertaken to deal with this problem may be obtained from the second annual report of the Water Pollution Research Board for the year ended June 30th, 1929 issued by the Department of Scientific and Industrial Research This board was set up in June, 1927, to prepare schemes of research for the prevention of pollution of rivers and other sources of water supply by trade effluents and sewage, and to supervise the investigations authorized by the department The problems involved are of growing significance to health authorities, particularly in densely populated areas, partly on account of the more widespread adoption of modern methods of sanitation, and partly because increasing supplies of water of good quality are being required for certain industrial processes Much valuable work has been done by the department not only within the scope of its immediate inquiries, but by encouraging investigation in different parts of the country, and in co-ordinating and applying the information obtained by other Government departments and by the research committees of various organizations The department co-operates with the Joint Advisory Committee on River Pollution, established by the Minister of Health and the Minister of Agriculture and Fisheries to deal with the legislative and administrative branches of the subject, and with the Scottish Advisory Committee appointed in March, 1928 In addition, monthly summaries of current literature consisting of abstracts of scientific and technical papers have been compiled since October, 1927, to assist those who are concerned with the improvement of water supplies Arrangements have now been made to publish these summaries, beginning with the number for January, 1930 Some idea of the practical value of the work of the board in co-operating with a particular industry may be obtained from the present report, which contains a description of its experiments in regard to the purification of the waste waters of beet-sugar factories In its previous report the board recommended that such factories should attempt to re-use water in various operations, and several have already modified their procedure or adopted processes designed for reducing the amount of effluent The importance of this investigation is indicated by the fact that the daily supply of water used by a factory dealing with 1,000 tons of beet a day amounts to three or four million gallons Experiments conducted during the year appear to have shown that a high degree of purification can be effected by employing a process of biological filtration As these experiments continue to furnish accumulations of miscellaneous data their ultimate results are expected to throw much light on the treatment of other types of waste waters Part of the work of investigators has been the collection of a large variety of organisms found in the filters About 800 bacterial cultures have been obtained altogether Each strain is being tested and classified with the object of isolating pure strains of specific value Another section of the report describes a comprehensive biological, chemical, and hydrographical survey of the River Tees which has been organized by the department in co-operation with a number of local bodies The main purpose of this pioneer survey, begun in April 1929, is to find out the interaction between a typically polluted river and the various effluents that are discharged into it, so that the quantity of polluted liquid that may safely be allowed to enter a river may be accurately determined Preliminary study of the biological aspects of the activated sludge process of sewage disposal was undertaken during the year at the London School of Hygiene and Tropical Medicine

London HM Stationery Office. 1930. 9d net

BRITISH POST-GRADUATE HOSPITAL AND MEDICAL SCHOOL

Appointment of Provisional Committee

THE Minister of Health, Mr Arthur Greenwood after consultation with the London County Council and the Senate of the University of London, has appointed a Provisional Organization Committee to proceed with the action necessary to secure the establishment of the British Post-Graduate Hospital and Medical School

The terms of reference of the committee are to consider and report, in pursuance of the statement made by the Minister of Health in the House of Commons on April 9th,* upon (1) the action requisite to lead up to the planning and construction of the medical school, and (2) the form of government appropriate to the hospital and medical school, with special reference to the position of the London County Council as the local authority responsible for the hospital, and to the position of the University of London in relation to the medical school

The chairman of the committee is Viscount Chelmsford The Ministry of Health will be represented by Sir George Newman, chief medical officer, and Mr M Heseltine, an assistant secretary, the London County Council by Dr Florence Barrie Lambert, Sir William Ray, Mr Angus Scott, and Mr L Silkin, and the University of London by the Rev Dr Scott Lidgett vice-chancellor-elect Mr Sidney L Loney, chairman of convocation and deputy chairman of the court, Mr H L Eason, superintendent and senior ophthalmic surgeon, Guy's Hospital and Dr Edwin Deller, principal of the university

The other members of the committee (all of them members of the medical profession) are Mr Donald J Armour, senior surgeon West London Hospital Ladies Barrett, dean of the London (Royal Free Hospital) School of Medicine for Women Mr Comyns Berkeley, surgeon, Middlesex Hospital, Sir Robert Bolam honorary physician to the Skin Department Royal Victoria Infirmary, Newcastle-on-Tyne and past Chairman of Council British Medical Association Dr H B Brackenbury Chairman of Council British Medical Association Mr H W Carson senior surgeon Prince of Wales General Hospital,

* British Medical Journal April 12th, p 777 and 752

Tottenham, Dr H G Dain, chairman of Insurance Acts Committee, British Medical Association, the Rt Hon Lord Dawson of Penn, Physician-in-Ordinary to the King, and physician, London Hospital, Dr H R Dean, professor of pathology, Cambridge University, Sir Walter M Fletcher, secretary of the Medical Research Council, Mr G E Gask, professor of surgery, London University, and surgeon, St Bartholomew's Hospital, Sir Thomas Horder, Bt, Physician-in-Ordinary to the Prince of Wales, and physician, St Bartholomew's Hospital, Dr F N Kay Menzies, medical officer of health for the County of London, Lord Moynihan of Leeds, President of the Royal College of Surgeons of England, consulting surgeon, Leeds General Infirmary, Mr H J Paterson, senior surgeon, London Temperance Hospital, and honorary secretary, Fellowship of Medicine and Post-Graduate Association, Dr Harold Pritchard senior physician, West London Hospital, and Sir Holburt Waring, senior surgeon, St Bartholomew's Hospital

Mr Heseltine will act as secretary, and all communications on the business of the committee should be addressed to him at the Ministry of Health, Whitehall, S W 1

THE BACTERIOPHAGE IN ASIATIC CHOLERA

AN INDIAN MEMOIR

AT the invitation of the Government of India, and with the aid of a grant from the Indian Research Fund, an investigation has been undertaken into the pathology and prophylaxis of Asiatic cholera by Professor F d'Herelle of Yale University, Major R H Malone, officiating director of the Pasteur Institute at Kasauli, and Dr M N Lahiri The result of their work has now been published in the form of a memoir (No 14) as a supplement to the *Indian Journal of Medical Research* The lines followed by the investigators included a study of the clinical pathology of this infection, of the environmental factors in its etiology, and of the properties of the vibrio strains isolated, determination of their reaction to bacteriophage cultures and of the effects of administering such cultures to cholera patients, and the careful examination of epidemiological evidence

It was found that a powerful bacteriophage strain could attach itself to cholera vibrios, eventually destroying them by means of a lytic ferment, a less potent strain caused the vibrios to contract a chronic disease, transmissible to their descendants, and modifying their characters more or less profoundly The bacteriophage, which is a filterable virus, is said to be a normal inhabitant of the intestine, and to be parasitic on the intestinal flora, having the power to adapt itself more or less rapidly to such invaders as the cholera vibrios In the course of an attack of cholera in man there occurs, consequently, in the intestine a secondary stage in which both the bacteriophage and vibrios are present, from cultures made at this time colonies of "ultra-pure" strains, and mixed "mutant" strains associated with the bacteriophage, were isolated This discovery, it is suggested, offers an explanation of the instability of the virulence of the vibrio of cholera, and of its variability as regards the reduction of nitrates, haemolytic power, and agglutinability, the variations detected in these organisms recovered from the intestine were reproduced *in vitro* by treating normal virulent vibrios with the bacteriophage Attenuation and complete loss of virulence are effected (1) progressively when the vibrio remains outside man, and (2) rapidly on account of the acquisition of resistance to the bacteriophage The multiplication in the intestine of vibrios with little or no virulence produces no symptoms of cholera, the virulent forms alone can invade and multiply within the intestinal mucosa, where they secrete cell-digesting enzymes, and also haemolysins for the red cells of man The deduction was drawn that an effective curative measure for cholera would be the administration of the bacteriophage which flourishes best in a slightly alkaline medium, experimental evidence was obtained that this was a sound line of treatment It is added, however, that since acute toxic bacillary dysentery (Shiga) is sometimes confused with cholera, it might be as well to use as a general therapeutic measure a mixture of anticholera and antidysentery bacteriophages Oral administration of the bacteriophage is said to be absolutely innocuous, so that even if the diagnosis is faulty no direct harm is caused by this treatment, it could be employed, therefore, in the more remote villages by ordinary hospital attendants in the absence of medical supervision Statistical figures are cited in support of these statements, it was found that the mortality rate of patients so treated was 8 1 per cent, comparing with 62 9 per cent among the controls When administered within six hours of the appearance of the first symptoms there were no deaths, administered between six and twenty-four hours after the first symptoms the mortality rate was 10 2 per cent, and after twenty-four hours it rose to 14 3 per cent The warning is given that the bacteriophage must never be given by subcutaneous injection

Epidemiological Researches

Interesting conclusions were reached by the investigators as regards the epidemiology of cholera in relation to the bacteriophage It is stated that, in a region where cholera has not broken out for several years, no vibrios and no bacteriophage strains possessing virulence for vibrios can be demonstrated In places where cholera has not occurred for two years at least, non-agglutinating vibrios may still be found, but bacteriophages virulent for the cholera vibrio are absent, or, at any rate, very rare In areas where cholera is endemic, as well as in other areas where the disease breaks out in epidemic form, carriers of non-agglutinating vibrios are very numerous during the months which follow the disappearance of the epidemic In these carriers bacteriophage strains also exist, which have a weak virulence for pathogenic vibrios but are capable of rapid exaltation even by a single passage with pathogenic vibrios, from these carriers also can be isolated bacteriophage strains which retain the power to destroy pathogenic vibrios In a region where an epidemic has raged for some time, as, for example, in the Punjab in 1927, four months after its onset three groups of human beings may be distinguished—namely (1) those persons in whose environment no bacteriophages virulent for the vibrio are found, this group being highly susceptible to infection, (2) those residing in places where non-agglutinating vibrios and bacteriophages virulent for pathogenic vibrios are present in wells or flies, these persons being "healthy carriers" and resistant to the epidemic and (3) those living in districts where cholera has occurred in the course of an actual epidemic, including convalescent carriers and resistant persons

When an epidemic first breaks out no bacteriophage strains are found in the water of wells, but they subsequently appear, at first in the flies found in houses where convalescents live, and then in the well waters, the epidemic ends when the bacteriophage becomes generally diffused These bacteriophage strains are highly virulent to vibrios from the very outset, and are directly derived from convalescent patients A few days after the end of the epidemic they rapidly disappear, being replaced by less virulent bacteriophage strains, which can, however, become exalted by a single passage at the expense of cholera vibrios A curious corollary is that the cholera patient spreads the pathogenic vibrios, and is therefore infectious, while a carrier spreads adapted bacteriophages, and, by this means, propagates the means of resistance, protecting crowds of previously uninfected individuals

Prophylaxis

Methods of isolation, sterilization of water, and preventive vaccination are only partly effective in the prevention of cholera, especially when the drinking water is obtained from wells The conclusion is therefore reached that the deliberate propagation of the bacteriophage offers the only effective means of preventing cholera in epidemic form Instead of waiting for the bacteriophage to be carried to the wells by natural means it would be preferable to introduce cultures of potent strains directly into the water supply of any group of persons in whom cholera has broken out Experimental work is reported

by the investigators to how that such a measure is in practice highly efficacious Indications are given of the lines on which the conclusions reached in this report might be experimentally tested on a large scale

Finally the wide practical application of this remedy, though difficult is not impossible and the concluding paragraph of the *report deserves quoting in full in view* of its suggestion to make use of human suggestibility in promoting health

It must be noted however, that the inhabitants of India generally speaking object to the addition of any material whatsoever to their drinking water, and it is admitted that if a measure is to be applied with any hope of success the public must accept it voluntarily Ther may perhaps be a means of making prophylaxis by the bacteriophag attractive Hindus consider the Ganges water to be sacred A laboratory for the preparation of cultures of bacteriophage might therefore be established on the banks of this river and the culture media prepared from its water indicating this fact in vernacular on the ampoules containing the bacteriophage cultures It is probable that Hindus would be pleased to see the water of the sacred river poured into their wells some of them would perhaps attribute the beneficial action to this, what does it matter if the object be achieved and the sum total of human suffering a little diminished?

EPSOM COLLEGE

Annual General Meeting

THE seventy seventh annual general meeting of the Governors of Epsom College was held at the office 4 Bedford Square W C on June 27th under the presidency of the chairman of council Dr RAYMOND CRAWFURD

The scrutineers Sir William Hale-White Mr W Cyril Tomlinson and Dr Septimus Sunderland reported that the successful candidates for pensioner ships and foundation scholarships were as follows

	Votes
Pensioners	
*Nicholson Mrs Agnes A	6 957
†Cadman Dr Frederick R	6 137
*Greenwood Mrs Mary M	4 471
†Humphrey Dr Edward A	4 334
Foundation Scholars	
Taylor David H	5 981
Dawkins Maurice	11 509
White John H B	10,389
Bull Gerald A	9 479

* Brodie Sewell Pensioner † Ordinary Pensioner

The secretary reported that Dr Edward W Forster who was at the head of the list of unsuccessful candidates would be *appointed an ordinary pensioner under* By law 16 at the council meeting which would be held immediately after the annual general meeting a vacancy having arisen

The annual report referred to the loss sustained by the College through the death of the Earl of Pembroke its president for twenty nine years and the election of Viscount Burnham to succeed him in that office While there was a moderate surplus on the income and expenditure account for the year the council urged friends of the College to renew their efforts to obtain fresh annual subscribers to make up for the loss of many generous supporters every year Special reference was made to the support given by the British Medical Association and its Charities Committee the Medical Insurance Agency and numerous Panel Committees The council also expressed thanks to the Editors of the *British Medical Journal* and the *Lancet* for assistance by means of appeals and for publishing official notices The following reference is made to the Scholarship Fund administered as a memorial to the late Editor of the *British Medical Journal*

The Medical Insurance Agency has generously handed over a further sum of £650 for the Dawson Williams Presentation Scholarship Fund of which a sum of £500 is to be devoted to the capital required to establish in perpetuity a scholarship of £150 a year in memory of the late Sir Dawson Williams C B E. M D for the necessitous son of a medical man or woman The benefits already awarded from this fund by a joint Committee of the Medical Insurance Agency and Epsom College have been greatly appreciated and it may be added that the intention underlying the foundation of this scholarship was to help a friendless boy especially one unlikely to be able to secure election to an Epsom College Foundation Scholarship

The progress of the new *sanatorium fund* has not been so rapid as the council hoped for, contributions received during the year amounting to little more than £2,200 the sum in hand on December 31st last was £7 765 The present sanatorium, being unsuited to its purpose cannot be worked economically and a sum of not less than £25 000 will be required for the new buildings the fittings and the furniture

The report was adopted on the proposal of the chairman, and Lord Dawson of Penn G C V O Sir Milson P K C V O and Mr T Hollis Walker K C were elected vice presidents of the College in recognition of valuable services rendered A cordial vote of thanks to Dr Raymond Crawfurd concluded the business

Scotland.

Extension of Dundee Royal Infirmary

THE formal opening took place on June 20th of a new maternity hospital erected at a cost of £38 670 an extension to Dundee Royal Infirmary The hospital was built and equipped by the late Mr Robert Bower Sharp and his brother Mr Frederick Bower Sharp of Hull of Tarvit and has been endowed by the latter and his sister Miss Sharp of Fernhall Mrs F B Sharp performed the opening ceremony Mr J C Burt LL D president of the Infirmary who occupied the chair recalled the fact that about thirty years had elapsed since the benefactor of the hospital Sir James Caird, had given them the maternity hospital A much larger and more modern building was now being inaugurated Dr James Haig Ferguson, president of the Royal College of Surgeons of Edinburgh remarked that it had been well said that a hospital was a treasury to which the rich could go with their poverty and the stricken with their needs Dundee was now in possession of a well-equipped and thoroughly up-to-date maternity hospital capable of dealing adequately with the need of its district This hospital would be an incalculable boon to the city for both women and infants it would also provide training of the highest standard for doctors nurses and midwives He could not [illegible] say that he had never seen a better arranged maternity hospital nor one more wisely planned The advantages of the close association of a maternity hospital with a gynæcological department could not be too strongly emphasized at Edinburgh it was hoped that there would be a similar close co-operation in the near future Dr Ferguson considered that in view of the fall in the birth rate it was more than ever necessary from an economic standpoint to do everything possible to conserve the child life of the country and hospitals such as this were a most important factor in achieving this end The voluntary hospital was an honour to their country and to their civilization In voluntary hospitals in Scotland last year 110,000 in-patients and 360 000 out-patients received treatment Dr John Parlane Kinloch Chief Medical Officer of the Department of Health for Scotland congratulated Dundee on this valuable addition to the Infirmary Forty years ago he said such health services as they had in Scotland to-day would have been regarded as Utopian dream He thought that the voluntary hospitals must remain the real medical pivot of the health service and there should be no rivalry but co-operation Obstetricians and specialists had to discover why women died and they needed institutions like the present one to put the new knowledge into effect The hospital would be a model for Scotland for many years

The new hospital is a ferro-concrete building of three storeys and has departments for the care of in patients and an ante-natal patients a district room and inquiry office a [illegible] and a lecture theatre suite Two wards each with twelve beds have been designed to admit the maximum amount of sunlight A cot hangs at the foot of each bed and a window in each will enable patients to listen in There are also [illegible] fitted with french windows and containing two beds Separate accommodation is provided for the delivery and [illegible] potentially septic patients and rooms are [illegible] for those [illegible] maternity cases born [illegible] labour and for patients suffering from [illegible] the delivery room is the centre [illegible] room instrument sterilizing [illegible] tudents gallery The [illegible] operating theatre [illegible]

1928, xxv, pp 403–416), which received editorial comment in the columns of the *British Medical Journal* (1929, ii, 676), is of particular interest in the present discussion He emphasized the necessity of regarding medicine, equivalent in England to the use of the term pathology, as an independent science, this status being preliminary to its being elevated to the position of a university discipline He explored the situation of medicine in respect to related sciences, and suggested arguments which seemed to justify the view that medicine can and should be regarded as belonging to the category of independent sciences He described what the advantages were for the study of disease, were it investigated actually by physicians, especially by those acquainted at first hand with the phenomena of disease, and trained to their observation, since it was obvious that neither chemists, physiologists, bacteriologists, nor anatomists could be supposed to regard such phenomena as primarily or exclusively their concern He attempted to show that in a rational sense an analysis of the processes exhibited by various groups of diseases necessarily preceded an attempt to rectify these processes in the enterprise called therapeutics Conceptually, therefore, there was, he thought, an advantage in distinguishing between the study of disease and of therapeutics There existed, of course, that aspect of therapeutics, which is usually designated as "roughly empirical," which had its proper and deserved place in the armamentarium of physicians, but which obviously was different in origin and design from "rational therapeutics," a good example of which was chemotherapy On account of these various considerations he believed, as a logical inference, that a difference distinguished practical (or the practice of) medicine from the study of disease It was the pursuit of the latter which was the occasion for constituting a university department of medicine

These theoretical points of view concerning the meaning of medicine have served as the "programme" of the university clinics of the University of Chicago They appear to resemble those which Sir Thomas Lewis now premises in his new proposals His plan, similar to that followed at Chicago, will, if actualized, bring into existence in England a reform which recognizes what in any case is a fact—namely, that the study of disease and the *practice* of medicine differ Systems or types of education designed to introduce men to a knowledge of these distinct, even if related, matters must also differ So instructed, men will, depending on their purposes and desires, be in a position to choose their callings with due regard to the various opportunities which medicine offers —I am, etc,

FRANKLIN C MCLEAN,
Director of University Clinics, The University of Chicago.

June 11th

ANTIMALARIA MEASURES

SIR,—In your issue of April 12th, which has just reached me, Colonel Gill's letter contains many incorrect statements—so many that I fear the limits of space in your *Journal* force me to comment only on the two which more particularly misrepresent my own position He states that Ross, and those who, like myself, think with him, are "completely satisfied with the state of scientific knowledge attained some thirty years ago" Colonel Gill has quite evidently failed to realize that an *epoch-making discovery* like Ross's is great not only in the knowledge which it gives, but in its opening so many other lines of research To my personal knowledge Ross has always encouraged this, and, were it necessary, I think I could prove from many sources that I, too, have also encouraged progress

Had Colonel Gill read with more understanding how practical and scientific work have been combined in Malaya to produce results of the highest value, he could not possibly have written as he has done So far from scientific work being neglected there, it has been so closely associated with practical work that it is, as someone said, an extension of "experimental medicine" that would have delighted the heart of Claude Bernard himself

How carelessly Colonel Gill reads is shown by an alleged quotation from an address I gave to the Royal Society of Tropical Medicine and Hygiene in 1924 A reference to page 152 of the *Transactions* shows that I said "They [the Commission on Mian Mir] thought that the work of the immediate future lay in patient and searching investigation, and in careful and continued experiment With that I entirely agree" According to Colonel Gill, I stated before the Royal Society of Tropical Medicine in 1924 that "the time was gone 'when patient and searching investigation and careful and continuous experiments' could serve any useful purpose in connexion with malaria" Further comment on Colonel Gill's accuracy is unnecessary

In closing I should like to whisper in his ear that the time for talking of "unsubstantiated claims" and saying that "it cannot be done" is passed, and that some of the more far-seeing in his service are wondering if it is the time to say, "We have been doing it all the time"—I am, etc,

Luanshya Northern Rhodesia, May 31st MALCOLM WATSON

EXCRETION UROGRAPHY

SIR,—In a recent discussion on excretion urography at the Royal Society of Medicine one of the speakers is reported to have stated that "no local cellulitis or reaction results, even if some does leak from the vein, so that 'bad arms,' such as occasionally result from tetraiodophenolphthalein, need not be feared" Since this form of radiological investigation would appear to have a wide field of usefulness, and may be largely exploited in the future, it would be a great mistake if the profession were to be misled by this statement into a false sense of security and resulting carelessness I have recently seen an extremely severe local reaction after the use of uroselectan resulting in local cellulitis, sloughing, and deep ulceration of the arm—a far more severe reaction, in fact, than I have ever observed after the intravenous administration of tetraiodophenolphthalein—and I consider that a very careful technique should be employed which ensures thorough washing out any remains of the drug in the tissues with saline —I am, etc,

Hove, June 26th C GUY WHORLOW

STORAGE OF X-RAY FILMS

SIR,—*The fire in an x-ray film store, as related by the Duchess of Bedford in your issue of June 28th (p 1198), can cause no surprise to those who are familiar with the properties of x-ray film, or nitro-cellulose* This substance is closely allied to gun-cotton, and is prepared by treating cellulose with nitric and sulphuric acids for certain periods

It seems remarkable that hospital authorities and radiologists are still allowed to store some hundredweights of these materials in the middle of a great city without any kind of regulation or control In my own garage I am not allowed to keep more than a small quantity of petrol, while in one of my hospitals I have sufficient inflammable material unprotected to demolish the building in a few moments My protests to the committee have been in vain In some hospitals the x-ray department is an extremely popular rendezvous with the members of the staff, it is appreciated that this place is one of the few in the hospital where one may smoke without hindrance or control It *cannot be long* before a cigarette will be thrown into the nitro-glycerin store and a disaster of the first magnitude herald a stringent Board of Trade control I do not think it probable that the hospital authorities or the Ministry of Health realize the dangers which can accrue in the storing of celluloid

An interesting point arises from your correspondent's letter as to whether a lead-lined safe is sufficient protection I must answer in the negative Nitro cellulose materials decompose at a rapid rate at a temperature of 100° C, even in the absence of air, the decomposition being exothermic For this reason spontaneous combustion can occur, the oxygen being supplied by the products of combustion In the event of celluloid being heated to higher temperatures, decomposition can be so rapid as to lead to explosion Glowing cigarettes are sufficient to ignite films, and heated water pipes will produce the same effects with an increased time period The matter has been carefully considered in America, where it will be recalled a large number of patients lost their lives in an x-ray film store fire last year

The only secure manner in which x-ray films may be stored is by enclosing them in a number of fire-proof and explosion-proof safes. These should be in turn ventilated by a shaft running to the open air, the whole unit being designed and installed under the guidance of one who is competent to advise.—I am, etc.,

Leeds, W.1, June 26th. L. J. H. ROTH.

THE OCCIPITO-POSTERIOR CAST

SIR,—I was interested to read Dr. A. H. D. Smith's letter in last week's issue of the *British Medical Journal* (p. 1126). I think that probably the face presentation was produced in the process of rotation and subsequent traction with forceps. This has happened in a few of my cases, but I have been able to rectify it. Care should be taken after rotation to see that the head is flexed.

I was called in yesterday to an occipito-posterior case. I did not see the case until late, and was able with difficulty, to rotate the head. Owing to a contracted pelvis forceps were difficult to apply and kept slipping. I left the patient for a couple of hours, and on my return had no difficulty in delivering a living child. The amount of moulding was very marked, the head being cylindrical. I find leaving the case for a couple of hours very useful and in the days of motor-car, not as difficult as it used to be.

Dr. Smith was good enough to mention my name with reference to inserting the upper blade first. It seems to me to be the natural thing to do. This is the most difficult one, especially in difficult cases, and the presence of the lower adds to the. In the old days the short time available was often very limited. I find that the upper blade when introduced hangs naturally forward, and the lower is easily put in behind, whereas if the lower blade is introduced first this has to be kept well back by an assistant while the upper is introduced. It is hardly necessary to say that the lower blade must be inserted behind the upper, but I was giving an anæsthetic for a friend and subjected him to trying this method. I found him struggling to get the forceps, he had inserted the lower blade in front of the upper.—I am, etc.,

Sharrow, June 26th. JOHN D. DAVIS.

SIR,—In your issue of June 28th (p. 1126) Dr. William recommends Kielland forceps for rotating the foetal head in occipito-posterior positions. From a limited experience of this instrument I think it is an efficient substitute for, and in some respects superior to, the classical axis-traction forceps.

In many occipito-posterior cases the occiput rotates anteriorly during labour, and in cases where it fails to do so spontaneous delivery frequently occurs. If the condition is found during pregnancy, troublesome and uncertain methods of rectification should never be employed, indeed, the condition need not be definitely diagnosed during pregnancy or even during labour provided progress is satisfactory. When labour occurs the head is frequently found well down in the pelvis at an early stage; if it remains high, disproportion should be suspected. If arrest occurs in the second stage in a primigravida the diagnosis is sometimes difficult, as a large caput frequently obscures the fontanelles. In a multipara it is much easier if examination is not deferred too long. In all cases *definite* diagnosis is possible by palpation, the ear under anæsthesia prior to application of the forceps.

The classical axis-traction forceps, which can be applied either in relation to the head or the pelvis, will effect delivery in practically all cases. If traction is carefully applied a complete tear of the perineum should never occur. If Kielland's forceps is used for rotation it is applied in relation to the foetal head with the indicators pointing backwards. It can be used however, with the indicators pointing forwards, delivery being completed without rotation. For this particular complication and for apparently normal cases in which there is undue delay Kielland's instrument is simpler and safer than the classical forceps.—I am, etc.,

Ewhurst, June 30th. E. CONDON, M.B., B.Ch., B.A.O., L.M.

ENDOGENOUS PUERPERAL SEPSIS

SIR,—Most authorities believe that the main source of puerperal sepsis is the mismanaged maternity case and that sepsis is introduced from without. A minority hold that infection from within is at least as important, and that teeth and tonsils are the main source of infection. The following history of a case of sepsis recently under my care is illuminating.

Mrs. T., aged 36, a healthy-looking woman, was confined on April 20th under ideal home conditions a trained nurse being in attendance as well as *myself*. She was a 2-para. Her confinement having been normal and delivery spontaneous. Pregnancy ran a normal course and no abnormal features were noted. The confinement was short in duration, no vaginal examination was made, and there was no intervention of any kind. On the third day the patient had a rigor, the temperature rose to 104·2° F. and pyrexia followed. On *examination nothing* was found in the urine, the breasts were normal, and lochia were not offensive. The uterus was undergoing normal involution. At the *end of a week* examination revealed a mass in the left broad ligament which by the fourteenth day had become palpable on abdominal examination. The lochia had now become definitely offensive. A diagnosis of an infected hæmatoma was made and the patient was removed to a nursing home for operation.

On the fifteenth day abdominal section was performed. The left ovary, broad ligament and tube were acutely inflamed. The ovary was ten times the size of an orange and full of pus. The broad ligament was thickened with cellulitis and phlebitis which extended a considerable distance up the ovarian vein. The uterus was quite small and was well involuted. At the junction of tube and fundus on both sides there was a tense swelling the size of a walnut full of pus. The interior of the uterus was perfectly clean and smooth. The right broad ligament, tube and ovary appeared to be normal. Hysterectomy being the only possible hope, I accordingly performed a subtotal hysterectomy and inserted a tube into the left pelvic pouch. The temperature gradually settled and the patient made a good recovery. Examination of the pus showed the infecting organism to be a streptococcus.

Examination of the patient's mouth showed that her lower six incisors and bicuspids were in a very bad condition and when examined it was established that the teeth were extracted and forwarded to Dr. Loveday of Manchester for examination and report. Culture gave a copious growth of haemolytic *streptococcus longus* of three main types: (1) Predominant, a small haemolytic *Streptococcus longus*; (2) a very haemolytic large *streptococcus longus* in smooth colonies; (3) a haemolytic *Streptococcus longus* of large type in rough colonies.

The evidence in this case strongly suggests that the source of infection was the teeth via the blood stream.—I am, etc.,

Kendal, June 26th. C. M. CRAIG, M.D., D.P.H., Hon. Asst. Surgeon, Westmorland County Hospital.

ETHER CONVULSIONS

SIR,—I feel indebted as will everyone interested in the subject to Dr. Stanley Sykes for his article on ether convulsions in the *Journal* of June 21st (p. 1123). In order to help in elucidating the problem of their cause I should like to categorize all the signs and circumstances of those cases I have come into contact with, which will form an essential supplement to his summary. Before doing so I would say again that I am sure that the condition can be easily prevented, and (I am tempted to reassert) cured, provided its onset is immediately recognized.

In many administrations removal at intervals of the frame and coverings, so allowing free access of fresh air, has the effect of quieting respiration, due in part, I suppose, to lessening the carbon dioxide concentration, and in part to stopping the ether vapour. It was this effect that led me to believe that an assumed hypercapnia was the chief cause of the convulsions; but in view of Dr. Langton Hewer's statement (mentioned by Dr. Sykes) that they have occurred during endotracheal administration the theory would become untenable. I should, however, be glad to hear full particulars from Dr. Hewer. Other considerations, too, are against such a theory; but in spite of this I feel that *faulty technique in the direction of overmuch covering and a forcing of the anæsthetic at the end of the second stage of induction*, most often appears as the effective cause.

(*a*) The patients are children and young adults almost always (my first case was a middle-aged woman).

(*b*) They nearly always suffer from a bacterial toxæmia (generally acute infection) but there are quite definite exceptions.

(*c*) They usually have a pyrexia.

(*d*) Pyrexia often develops, apparently as a result of the convulsions

(*e*) In most cases ether has been the only agent used In one, in which convulsions were beginning none had been given

(*f*) History of epilepsy has not always been sought but has often been negative

(*g*) Oxygen has generally, or always been added

(*h*) As a rule if not always the face of the patient has been suffused with blood, and he has shown the sthenic appearance common during etherization Blood pressure has not been taken

(*i*) The onset usually is early during the operation when anaesthesia is fully established In many cases however, it is later

(*j*) It begins either by energetic breathing becoming irregular (especially inspiration) or in a twitching of the mouth or of the eyelids or by a flexion of the elbow, first on one side and then on the other, causing a steady rise of hand and forearm from the table (I have seen this twice as the first sign) or in a twitching of arms or shoulders Occasionally cyanosis is the first sign

(*l*) Blueness (the breathing being interfered with by the convulsions) becomes increasingly evident

(*l*) Deepening of the narcosis does more harm than good

(*m*) Convulsions are severe, sustained general, and epileptiform

(*n*) They are always typical

(*o*) Death occurs from exhaustion insufficient oxygenation persisting until the end in spite of cessation of convulsions and plentiful supply of oxygen

(*p*) It seems probable that the issue of every case would be fatal if the administration were not suspended or the method altered

(*q*) Recovery from the narcosis is delayed even after a short attack

(*r*) Two cases (I have heard of another)—all fatal—had recurrence of the convulsions later on in bed, one after an apparently complete recovery

(*s*) In one case I purposely resumed the administration of ether by the same method without ill effect

These considerations may refute all theories so far advanced but if faulty method developed in recent years be (as I feel confident) the chief factor in what way could it operate? Dr Sykes thinks the oxygen should be analysed but having regard to the case just mentioned (*s*) it could hardly throw any light on the subject—I am etc,

Victoria Park, Manchester, June 24th K B PINSON

SIR,—Dr Stanley Sykes's interesting article on ether convulsions in your issue of June 21st, and the apparent rarity of the condition prompt me to record a case which I had a few weeks ago, and which presents one or two interesting features in connexion with the various hypotheses which have been put forward to explain the etiology of this condition

The patient was a girl aged 17 who was having a fractured tibia plated The fracture had previously been compound and though the wound was clean at the time of operation the patient had been running a temperature for some time Ether and oxygen were administered by Boyle's apparatus and the anaesthetic proceeded uneventfully for over half an hour except that the patient, though not very deeply anaesthetized breathed very shallowly a fact which I attributed partly to the liberal supply of oxygen which she was having The patient then started to have clonic spasms, which increased in severity and became generalized

I must confess that at the time I was not fully aware of the serious prognosis of the condition and as the operation was by then almost over, I turned off the ether and turned the oxygen on full, with the idea of washing out any remaining ether vapour from the respiratory passages The spasms lasted for about two minutes and then became less and ceased and the patient was apparently none the worse At a previous operation three weeks previously, at which ether was used there were no spasms

This case, which must be classed as one of the "septic" type, occurring like most others, in a young adult, presents two interesting features The fact that, at a previous operation three weeks previously, no spasms occurred is strongly against the "idiosyncrasy" hypothesis, though it may be supposed that the toxaemia following the compound fracture increased the susceptibility of the patient to ether clonus The fact that the spasms ceased actually while the patient was being given oxygen "full blast" would appear to be against Mennell's "over-oxygenation" hypothesis—I am, etc,

Addenbrooke's Hospital, Cambridge, June 26th J I SAPWELL

INVASION OF THE GALL-BLADDER BY ASCARIS LUMBRICOIDES

SIR,—Drs Wood Power and Johnston (*British Medical Journal* (June 14th, p 1086) find that in man, invasion of bile ducts by *Ascaris lumbricoides* is not infrequent whereas invasion of the gall-bladder is rare In young swine *Ascaris lumbricoides* is frequently found in the small intestine whence it commonly migrates into the bile ducts, but invasion of the gall-bladder and of the pancreatic duct is, I believe, rare Two specimens in the Museum of Pathology Royal Veterinary College demonstrate very clearly migration of the worms from the duodenum up the bile ducts into the gall-bladder and hepatic ducts No A12c2 0 shows chronic cholecystitis and cholangitis with ascarids thickly packed in the distended bile duct and lying free within the gall-bladder and hepatic ducts The subject was a young adult male pig having a history of progressive emaciation terminating in refusal of food for three days when it was slaughtered There was no jaundice No A12c2 01 shows a similar invasion, but the inflammatory changes in the biliary tract are slight The subject was a male pig aged 11 weeks which was slaughtered for food as a healthy animal, there was no jaundice—I am etc,

Department of Pathology, Royal Veterinary College, N W June 23th TOM HAPE

AMPUTATION AND ARTIFICIAL LIMBS

SIR,—I was much interested in the report of the Royal Society of Medicine's discussion on amputations (*Journal*, April 12th, p 693) and as an amputee I should like to give my ideas about the subject I quite agree about the Syme amputation it has not been a success on the whole With high amputations I believe in giving all the end-bearing possible if there is not sufficient below the knee one should try to give a knee-bearing It may not look so pretty and the prosthesis is longer than the natural leg, but the patient can walk and work far better One of the best thigh amputations I know was done by Dr R B Wade about 1918 in Sydney He amputated about three inches above the knee and tacked the patella on to the end The stump is excellent and all the weight is taken on the end, with the result that the amputee can stand all day walk long distances and play a really good game of doubles tennis His weight is about 13 stone

I have seen all the fitting at the Commonwealth Artificial Limb Factory for seven years, where all the legs, arms, surgical boots, and appliances are made for the soldiers With an end-bearing stump fitting is easy as there is less weight and friction on the tissues about the ischium I have a bad stump and have to take all the weight on the ischium and in the summer, with the temperature between 75° and 95° F, and humidity anything up to 90, the skin chafes and gets sore It is most important to provide as large an area for pressure about the ischium as possible to save chafing A good ointment for rubs and pimples is yellow vaseline with 20 per cent quinine sulphate a little should be put on the sock and allowed to rub in during the day—I am etc,

Sydney, N S W May 22nd A H MOSELEY, D S O M B, Ch M, D P H

HEREDITARY FACTOR IN HAY FEVER

SIR,—There is some evidence that susceptibility to hay fever is an hereditary character It is also a character usually well marked and comparatively easy to trace among members of a family At this time of the year many medical practitioners must meet with hay fever patients whose genetical history could be discovered without difficulty Should any of your readers come across such cases and be willing to obtain records of the incidence of hay fever among members of the family over say, four generations, I would be interested to receive such records, which I am collecting—I am, etc,

Bacteriology Department, Rothamsted Experimental Station, Harpenden, June 27th H G THORNTON, D Sc

DRUG TREATMENT OF MEASLES

SIR,—I should like to endorse the remarks made by Dr H J Clutterbuck in the *British Medical Journal* of June 21st regarding the treatment of measles by the powder consisting of aceto-salicylic acid, compound ipecacuanha powder, and phenacetin The results have been most gratifying Two years ago I had the opportunity of using this method of treatment in fifty cases There was a very rapid improvement in almost every case The cough was markedly relieved and it was seldom necessary to give the powder during the night as the patient slept well All these cases occurred in boys between the ages of 10 and 18 years Up to the age of 16 the doses given were aceto-salicylic acid 2½ grains, pulv ipecac co 1½ grains phenacetin 1½ grains every four hours In patients over 16 the amounts were doubled.—I am, etc,

Hereford June 23rd A S HENDRIE, M B Ed

SPINAL ANÆSTHETICS

SIR,—Mr H H MacWilliam, in a letter published in the *Journal* of June 21st (p 1154), has pointed out a slight inaccuracy in my article on spinal anæsthesia (June 14th, p 1003) The statement that "planocain . . . is really strychnine-free spinocain" is perhaps not quite correct The planocain we used was not the same as the product usually supplied under that name by May and Baker and which Mr MacWilliam has probably used in his case These solutions have the following formulæ

No 1 Solution

Panocain (novocain)	0·2 gm
Glucin	0·0025 gm
Alcohol (5 per cent)	to 2 c.cm

No 2 Solution

Fresh drawn cerebro-spinal fluid	0·5 c.cm
Planocain	0·01 gm
Normal saline	to 1 c.cm

Recently May and Baker have issued a new product called duracaine light solution, made up in 3 c.cm and 1 c.cm. ampoules respectively The 1 c.cm ampoule has the same formula as the No 2 solution quoted above, but the 3 c.cm ampoule contains the following constituents

Planocain	0·1 gm per c.cm
Glucin	0·00325 gm per c.cm
Ethyl alcohol (15 per cent)	to 3 c.cm

We have used duracaine in the last thirty cases, and have found it the most satisfactory of any solution so far —I am, etc,

Norfolk and Norwich Hospital, June 23rd R A GRANT

JAMES MACKENZIE

SIR,—With reference to my lecture on "James Mackenzie and his message," which was published in your issue of June 7th, I should like you to correct one small error On page 1035, among several names of men associated with Mackenzie, occurs that of Cushing This, of course, should read Cushny I was referring to the late Professor Cushny, whose work on digitalis is so well known.—I am, etc,

Liverpool June 21th JOHN HAY

AUTOMATIC MACHINES FOR SALE OF DRUGS

PHARMACEUTICAL SOCIETY'S FIRST CASE

THE Pharmaceutical Society of Great Britain, which recently issued a warning on the dangers of automatic machines for the sale of drugs (*British Medical Journal*, January 18th, p 134), brought, on April 21st, a friendly action at the Wood Green County Court, against Harry Ronald Watkinson, a chemist and a member of the society, of Lord Hill Lane, Tottenham, claiming £5 penalty for breach of the Poisons and Pharmacy Act 1908

Mr Glyn Jones for the Pharmaceutical Society sought the ruling of the judge (Judge Crawford) on a new and important point arising under that Act He said that Mr Watkinson, the defendant was a loyal member of the society, and no question was cast on him as a chemist, but the society thought it undesirable that the public should have access, without the intervention of a qualified chemist, to all manner of poisons which might be offered for sale by means of automatic machines The question was whether the sale of poisons from these machines was lawful Bottles of lysol bearing a statement to the effect that they contained 50 per cent of cresol, and labelled "Poison" were bought by an inspector in the employ of the society from an automatic machine outside Watkinson's shop The point made was that the sale of these poisons was the carrying on of the business of a chemist and druggist, which must in accordance with the statute, be conducted by a qualified chemist, which an automatic machine was not He added that the use of these machines was enormously extensive and if they were contrary to law the decision of the court would be of far reaching importance

At an adjourned hearing, on May 21st Mr George Pollard representing the chemist said that his defence was that although the sale complained of fell within the range of general supervision it did not fall within the particular point of supervision required for a sale of poison for which the purchaser had to sign a book recording the sale of dangerous drugs

Judge Crawford gave a considered judgement on June 25th He found in favour of the Pharmaceutical Society for the amount claimed (£5) with costs He said that the defendant in his view, carried on the business of a chemist and druggist through the medium of an automatic machine, from which he sold to the public a dangerous poison The evidence satisfied him that any child tall enough to place a coin in the slot and take a bottle of lysol could do so without the knowledge of the defendant or any person in his employment. Beyond all question, this ought not to be allowed. A highly qualified analyst had found that the bottle contained over 47 per cent. of homologues of carbolic acid, and no supervision had been exercised over the sale of the poison The sale of such a dangerous poison as lysol certainly ought to be part of the business of a chemist and druggist rather than of any other trader

Obituary

DR CECIL WEBB JOHNSON who died in London on June 23rd, was born in 1879 at Stoke-on-Trent, where his father Dr Samuel Johnson was medical officer of health, his brother is Mr Alfred Webb-Johnson, surgeon to the Middlesex Hospital He was educated at Owens College Manchester, and the London Hospital, graduating M.B, Ch B Manch in 1903 After serving as clinical assistant at the Chelsea Hospital for Women he was appointed, in 1906, assistant medical officer to the Staffordshire County Asylum For some years before the war he had held a commission as Captain R A M C T F, and at the Annual Meeting of the British Medical Association at Aberdeen in 1914 he acted as joint honorary secretary of the Section of Naval and Military Medicine and Surgery, opening a discussion on common ailments in camp, their prevention and treatment After the outbreak of war he was sent to India, where he served with the rank of major, and held in turn the posts of civil surgeon and officer in charge of the station hospital at Dum Dum, specialist in midwifery and diseases of women and children, 8th Lucknow Division and medical officer at station hospitals in Calcutta, Lucknow, and Allahabad On returning to England in 1919 he began private practice in London, and was for some years clinical assistant at the National Hospital for Diseases of the Heart The interest he had taken while in India in dietetics and disorders of metabolism led him to write a number of popular works on diet, obesity, and kindred subjects Dr Cecil Webb-Johnson was also well known as a composer of waltz tunes and other light musical pieces

We regret to record the sudden death, on June 26th, of Dr C J B MACFADDEN of Hampstead, at the age of 59 He was educated at the University of Edinburgh, where he graduated M.B C.M. in 1894 proceeding M D four years later He held the appointments of medical officer to the Hampstead Provident Dispensary, divisional surgeon to the Metropolitan Police since 1919, and medical referee under the Workmen's Compensation Act for the district of the Marylebone County Court He was also assistant commissioner of the Prince of Wales's district of the St John Ambulance Brigade, and honorary life member, examiner,

and lecturer of the St John Ambulance Association He was a member of the executive committee of the Hampstead Division of the British Medical Association, and one of the representatives of the Division on the council of the Metropolitan Counties Branch, and was an ex-president of the Hampstead Medical Society Dr MacFadden had served as surgeon to the Cedar Lawn Military Hospital, medical officer in charge of the American Hospital, Caenwood Towers medical officer of the Officers' Recuperative Hostel, Oakhill Lodge, and surgeon to the British Red Cross Hospital, Bulgarian Relief Section in the second Balkan war, and was appointed Chevalier avec Couronne de l'Ordre du Merite Civil du Bulgarie He took great interest in local affairs and was a member of the Hampstead Borough Council for thirteen years, during which period he had served on a number of committees He was chairman of the Maternity and Child Welfare Committee for two and a half years and chairman of the Public Health Committee from 1920 to 1922 and again since 1929 On the day of his death he had been discussing with the officials a report of his committee till 5 P.M. and subsequently attended a patient At the meeting of the town council held on the evening of June 26th when the mayor announced the sudden death of Dr MacFadden the members stood in silence as a sign of respect For his services in connexion with the European war he received the decoration of O.B.E. Dr MacFadden is survived by his widow one son and one daughter

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons gave three days this week to the committee stage of the Finance Bill A discussion on housing arose on June 30th and July 4th was set aside for the report stage of the Road Traffic Bill Consideration of the Housing Bill by a standing committee was completed on July 1st The House of Lords advanced several minor bills during the week

The Parliamentary Medical Committee met on July 1st and arranged to send a deputation to the Minister of Health next day to advocate the establishment of a central advisory committee on rheumatism clinics

On July 1st Mr R J Russell presented a bill to amend the *Food and Drugs (Adulteration) Act 1928* and to control the sale of cheese other than whole milk cheese

The Hours of Industrial Employment Bill has been withdrawn

Miners' Nystagmus

On July 1st Mr SHINWELL told Miss Lee that miner suffering from nystagmus were in the same position under the Workmen's Compensation Acts as workmen disabled by accident or other industrial disease He was aware of the difficulties to which they were exposed in obtaining re-employment particularly in the present condition of the industry and his Department was still considering with the Home Office what steps might be taken to help them in this respect Clearly the best remedy was to diminish the incidence of the disease and investigations with that object were in progress While medical opinion was by no means unanimous it was generally agreed that defective light was a contributing factor, and it was satisfactory to note that with the encouragement of his Department, improved lamps were being introduced at many collieries

Housing

In reply to Sir Kingsley Wood, on June 25th, Mr GREENWOOD stated that, during the year ended March 31st 1928, 18 slum clearance schemes had been confirmed 8 completed, and 98 were in course of execution at the end of the period During the following year 10 schemes were confirmed, 14 completed, and 91 were in execution Up to March 30th, 1930, 17 schemes had been completed and 77 were in execution The number of buildings acquired by local authorities in approved slum clearance schemes for the period between June 30th, 1929, and March 31st, 1930, was approximately 700 Mr Greenwood further said, on June 25th, that he was aware of the overcrowded condition of many tenements, but had not received specific reports relating to their verminous condition He did not propose to seek further powers under Section 46 of the Public Health Act, 1925, as local authorities had found their powers adequate, and there was no general demand for further legislation

On June 30th the House of Commons in committee discussed the vote of the Ministry of Health for housing and administration under the National Health Insurance Acts

Dr VERNON DAVIES said that of all the failures of the Government the most colossal was that in regard to housing

Viscountess ASTOR asked if the Ministry of Health had considered the question of securing sites for nursery schools She also asked what had been done in regard to the prevention of maternal mortality At present 3,000 women died every year in childbirth, and some members had a suspicion that the money which might have gone towards the work of prevention had been spent in other ways

Miss LAWRENCE replying to the debate said it was true that the Government advised local authorities to hold their hands in regard to slum clearance until the new Housing Bill had been passed The Government was proposing a shortening of procedure, and considered that the local authorities would gain by waiting for it

---

National Health Insurance.—Mr GREENWOOD told Mr Albery and Sir Kingsley Wood on June 26th, that he had not received any resolution from the recent co-operative congress on the continuance of the regulations of the Ministry of Health prohibiting the payment of co-operative dividend on national health insurance prescriptions but he was aware of the discussion which took place, and the matter was receiving his attention

Silicosis in Carmarthenshire.—Mr SHINWELL replying to Mr Hopkin on July 1st said that the inquiry by the medical officer of the Mines Department into silicosis in the Cross Hands district of Carmarthenshire was proving much more laborious than had been anticipated Although a great deal of relevant data had been collected, the results on examination indicated the necessity for further inquiry

Cost of a National Maternity Service.—On July 1st Mr GREENWOOD told Mr Freeman that data required for framing even an approximate estimate of the cost of providing a national maternity service ensuring the services of doctor, midwife, and anaesthetic administration, were not yet available

Mental Hospitals.—Mr OLIVER BALDWIN asked the Minister of Health, on June 26th, to consider setting up medico-psychological departments in mental asylums, both criminal and non criminal, in order to attempt the effecting of cures Mr GREENWOOD said he could not consider the proposal without a more precise indication of the proposed department and of the necessity for its establishment, having regard to the medical services already available in mental hospitals

Private Mental Institutions.—Replying to Mr Maclean on June 26th, Mr GREENWOOD said the conditions under which patients were treated in private mental institutions were examined by the Visiting Commissioners of the Board of Control, who had a duty to inquire, among other things into the fees paid The Commissioners satisfied themselves that the fees paid were generally reasonable for the accommodation and treatment supplied He did not propose to take power to compel licensees to submit their accounts to a Government department for examination

Lunacy and Divorce.—Mr MACDONALD stated, on June 30th, that he was unable this session to grant facilities for the passage of a bill to make certified lunacy of five years and upwards a ground for divorce

Physically Defective Children.—In a reply to Mr Foot, on June 26th, Sir CHARLES TREVELYAN stated there were 557 blind children under the age of 16 not attending any school or institution on December 31st, 1929 The corresponding number of deaf children was 305 and of cripples 5,461 These figures included children below school age and those temporarily prevented from attending special schools, and there was no need for special accommodation

Prevalence of Mosquitos.—On June 24th Miss SUSAN LAWRENCE replying to Sir W Davison, said that the Minister of Health was advised that the number of mosquitos in this country fluctuated from year to year according to the climatic conditions, but did not show any general increase In the present year some species (especially the sylvan species) were unusually prevalent The Ministry of Health, in collaboration with the Natural History Museum, had given attention to this matter for some years past, and a pamphlet on *British Mosquitos and their Control* had been published, which contained advice on the best methods of combating mosquito pests The Ministry was also prepared, on request, to advise local authorities on the matter

Poisonous Liquor.—Mr ADAMSON told Mr McElwee, on July 1st, that he had received a report on "red biddy" from the chief medical officer of the Department of Health for Scotland

Medical Records of Adolescents.—On July 1st Mr HORE BELISHA asked the Minister of Health if his attention had been drawn to a recommendation of the medical officer for Plymouth, in his recent report on the health of that city that children aged 15 should immediately become insurable, so that their school medical records could be passed to panel doctors, thus avoiding the present year's gap in health supervision Mr HAYES, who replied, said that, in the event of provision being made by legislation whereby the minimum age for entry into insurance would coincide with the normal school leaving age, the question of the transfer of the relevant medical records would receive consideration

Smoke Abatement.—Mr GREENWOOD stated, on June 26th, in reply to Sir N Grattan Doyle, that 116 local authorities had made by-laws on the subject of smoke abatement This left 1,652 without by-laws, but these were largely districts where few or no manufacturing processes were found He found it unnecessary to exercise his power of forcing local authorities to make by-laws

Universities and Colleges.

UNIVERSITY OF OXFORD

At the Encaenia held on June 25th the honorary degree of D Sc was conferred on Sir Arthur Keith M D LL D F R S Conservator of the Museum of the Royal College of Surgeons of England

At a congregation held on June 26th the degree of B M was conferred on G Campbell

Osler Memorial Medal

The Osler Memorial Medal for 1930 has been awarded to Sir Wilmot F Herringham K C M G C B D M F R C P This bronze medal is awarded every five years to the Oxford medical graduate who has, in the opinion of the Board of Awarders made the most valuable contribution to the science, art, or literature of medicine and who has not previously received the medal

The Theodore Williams Scholarship for 1930 has been awarded to Mr H N Davis (University)

UNIVERSITY OF CAMBRIDGE

The Master and Fellows of Corpus Christi College have awarded the Copeman Medal for research in medical and biological sciences to Dr R Hilton, a distant physician St Bartholomew's Hospital This is the first award of the medal presented by Dr S Monckton Copeman F R S formerly a scholar of the college It was designed by Mr T H Paget and struck by the Royal Mint

The following candidates have been approved in the examinations indicated

M Chir.—A. Simpson-Smith C F Tucke

UNIVERSITY OF LONDON

KING'S COLLEGE

Dr J H Moynihan has been appointed honorary demonstrator in anatomy

ST THOMAS'S HOSPITAL MEDICAL SCHOOL

H.R.H. the Duke of Connaught presented the prizes to the successful students of St Thomas's Hospital Medical School on June 25th In the course of his remarks he recalled the fact that he was present at the laying of the foundation stone and at the opening of the hospital of which he was president He mentioned that £570 000 was now needed for a new school and new out patient and special department Professor L S Dudgeon, dean of the school, reported that the number of students had never been at a higher level, it was anticipated that the figure might be exceeded next year The examination records were very satisfactory, as St Thomas's men showed a percentage of passes well above the average

UNIVERSITY OF DURHAM

On June 26th the honorary degree of D C L was conferred upon Lieut.-General Harold B Lawson C B C M G D S O Director General Army Medical Services

UNIVERSITY OF MANCHESTER

The following appointments are announced Lecturer in Experimental Physiology, Walker Schlapp M B Ch B, Ph D, Assistant Lecturer in Anatomy J M Yoffey, M Sc, M D Demonstrators in Anatomy, F N Marshall, M B, Ch B D Sheehan, M B Ch B, Demonstrator in Human Physiology L B Winter, M D

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A HUNTERIAN Lecture on "Hydatid disease—some interesting complications" illustrated by lantern slides will be delivered in the theatre of the College Lincoln's Inn Fields W C, by Professor Harold R Dew on Thursday, July 10th at 2.45 p.m

Medical News.

THE Queen has addressed a message of congratulation and goodwill to the National Baby Week Council on the occasion of the fourteenth National Baby Week, which began on Tuesday, July 1st

THE Fellowship of Medicine and Post Graduate Medical Association announces that from July 21st to August 3rd an *afternoon course in infants' diseases*, with special reference to dietetics and nutritional disorders, will be given at the Infants Hospital under the direction of Dr Eric Pritchard. The sessions will last from 2 to 5 o'clock, and will consist of demonstrations in the out patients department, round table consultations etc , visits will be paid to the Nursery Training School the V D centre at Thavies Inn and the United Dairies pasteurizing plant at Willesden, fee for the course 3 guineas As August is generally regarded as a vacation month it is not possible for the Fellowship to arrange for many special courses but there will be a course lasting one week at the Brompton Hospital from August 11th to 16th, when instruction will be given throughout the day from 10 a.m , and an afternoon and evening course in genito-urinary diseases at All Saints' Hospital, Vauxhall Bridge Road S W , from August 5th to 30th This course will consist of demonstrations on cases, cystoscopies, etc , fee £2 12s 6d For those not desirous of following a special course the Fellowship provides a general course admitting to the clinical practice of its associated hospitals A programme setting out the clinics under subject headings is provided, leaving the holder of the comprehensive ticket free to make out his own time table The course can be begun on any day of any week Graduates should write to the Fellowship of Medicine, 1, Wimpole Street, W 1, for all syllabuses and tickets of admission

THE nineteenth annual meeting of the British Waterworks Association will be held in Liverpool from July 9th to 11th inclusive Among the papers to be read is one by Professor J M Beattie, bacteriologist to the City and Port of Liverpool, on the value of regular systematic examination of water with special reference to the interpretation of results

MR HENRY TONKS F R C S, has just retired from the Slade Professorship of Fine Art in the University of London, which he had held since 1917 His inspiring work as a teacher at the Slade School during the past forty years and his own accomplishment as an artist in various *mediums*, formed the subject of a valedictory leading article in the *Times* of June 25th

THE results of an investigation into the reflection from road surfaces have been published by the Department of Scientific and Industrial Research The object of the inquiry was to obtain more precise data in regard to the efficacy of present systems of street lighting which generally assume that the brightness of a road surface is approximately proportional to its illumination Recent studies of the subject, particularly in America, have indicated that uniformity of illumination of a road surface does not imply a uniform brightness—a factor involving the consideration of angles of light incidence and of different lines of view Thus the driver of a vehicle is chiefly concerned with the appearance of a street a considerable distance ahead The present investigation consisted of a systematic series of measurements of the reflection factors of four different kinds of road surfaces in common use in this country In some instances where the incidence of the light was very oblique, the brightness was found to be several hundred times as great as that based on the assumption of perfect diffusion Some practical applications of the theory are given in the report, which is illustrated by graphs and diagrams Copies are obtainable at H M Stationery Office, price 6d

AT a meeting of the Paddington Medical Society to be held at 3 p.m on July 8th, at *the Great Western Hotel*, Paddington, Dr G E Oates will deliver an address on public health topics of general interest A resolution for the appointment of a section in connexion with the *National Health* Insurance Acts will be considered and reports will be received from representatives on *other bodies* Membership of the society is open to all medical practitioners *residing or* practising in the Metropolitan borough of Paddington. Particulars may be obtained from the honorary secretary, Dr J Cohen 23, *Westbourne Park Road* W 2

MESSRS GEORGE ALLEN AND UNWIN Ltd , have taken over the agency, for Great Britain, Northern Ireland, and the Crown Colonies, of League of Nations publications, hitherto held by Messrs Constable and Co Messrs Allen and Unwin will conduct all League of Nations business from 38 Great Ormond Street, W C 1 (Museum 1439) and not from 40, Museum Street The London office of the League of Nations, for all purposes except the sale of publications, remains at 16 Northumberland Avenue, W C 2.

THE tenth Belgian Congress of Neurology and Psychiatry will be held at Liège, under the presidency of MM R Titeca and B Dujardin, from July 28th to 30th, when the following subjects, among others, will be discussed Angioneurosis, by MM Rivry and Moreau, and congenital disturbances of speech, by M Ley Further information can be obtained from the general secretary, M Alphonse Leroy, 18, Rue Beckmann, Liège

THE sixth Congress of the German Society for the Study of Accidents, Insurance, and Welfare Medicine will be held at Breslau on September 26th and 27th, under the presidency of Dr P Jotthowitz The principal subject for discussion will be trauma and the vertebral column

THE fourth International Congress for Individual Psychology will be held in Berlin from September 25th to 28th, and will open with an address by Dr Alfred Adler

THE Italian Congress of Internal Medicine will be held at Rome in the first fortnight of October, when the following subjects will be discussed acute pulmonary oedema, introduced by Professor Cesare Frugoni, differential diagnosis between visceral neuroses and organic disease, introduced by Professor Nicolas Pende, diagnosis and treatment of haematuria in conjunction with the Italian Society of Surgery introduced by Professor Ferraia and Professor Gino Lusio military service and constitutional biological and pathological factors, introduced by Major Cassinis

DURING the first five months of this year there were 132 cases of trichinosis in California, as compared with only 33 in the whole of 1929 Four of the 132 cases were traced to the consumption of smoked bear's flesh

QUERIES AND ANSWERS.

TINNITUS AURIUM

"J. T." wishes to know the cause of singing in the ear at night with some deafness, but no pain, after driving with the window open in a saloon car What is the best treatment for this complaint?

*** The following simple suggestions may be made (1) examine meatus and membrana tympani, (2) inflate Eustachian with catheter, (3) close window of car.

INCOME TAX

Exemption of Residents Abroad

[illegible] inquires whether income tax ceases to be chargeable on [illegible] of persons leaving this country and residing abroad [illegible] in the Channel Islands—if the income is from [illegible] Government stock, if so how the exemption is obtained, the income it can be claimed

—for example, is that persons who have no residence [illegible] British Government [illegible] respect of income arising in the [illegible] and from what date [illegible] respect of other income Certain

*** The general rule [illegible] example, the 5 per cent War Loan in this country are liable [illegible] ng that income tax would United Kingdom, but not in re[illegible] T S" terminates his Government stocks, however—for Loan—were issued with the understanding not be charged on interest thereon while was resident abroad If, therefore, residential connexion with this country—prolonged annual visits might be regarded as keeping that connexion in being—and invests his capital in foreign investments or British 5 per cent War Loan, he will not be liable to British income tax thereon If the War Loan stock is held in registered or inscribed form, the interest will be paid in full, if it is in the form of bearer bonds, tax will presumably be deducted and he will have to claim repayment through the authorities at Somerset House The title to exemption will operate as from April 5th following the termination of his residential connexion with this country

LETTERS NOTES ETC

THE "COIN-CATCHER" A CORRECTION

SIR JAMES DUNDAS GRANT writes My attitude with regard to the coin catcher" and endoscopic extraction is incorrectly represented in the report of the proceedings of the Laryngological Section of the Royal Society of Medicine in the *Journal* of June 28th (p 1175) My remarks were mainly occupied with the advocacy of the employment of Killian's (or Brüning's) special small laryngoscope for children, with which I have removed a coin from a child's oesophagus when the ordinary sized instrument had, in the hands of an experienced examiner, failed to expose it.

MEDICAL RELICS OF POLAR ACHIEVEMENTS

THE makers of history in Polar exploration have been men of various nationalities—English, Scottish, Irish, Australian, Canadian, American, Norwegian, Italian—but they have all relied on British medical equipments Those who visit the Polar Exhibition which is being held at the Central Hall Westminster, from July 2nd to 15th, will find an interesting exhibit of the medicine cases of many Arctic and Antarctic explorers Among these is the medical belt of Fridtjof Nansen who attempted to drift across the North Pole Basin during 1893-96 What remains of the actual equipment of Jackson, the leader of the Jackson-Harmsworth expedition in 1896, sent to rescue Nansen, is also shown Amundsen's case, too, is on display, together with, among others, those of Scott, Shackleton, Wilkins, Mawson, Peary, the Scottish National Antarctic Expedition (Bruce), the Canadian Arctic Expedition (Stefansson) All these exhibits are the original "Tabloid" medical equipments supplied by Burroughs Wellcome and Co

A SCHOOLBOYS' CAMP ON THE BROADS

DR H J STARLING (Norwich) writes As it seems to have escaped the attention of public school boys' parents resident in the North may I ask the hospitality of your columns to explain that the Broads Cruising Association has for the last six years been running a fortnight's camp for public school boys on the Norfolk Broads at Thurne, near Acle This is a training camp which is run to give its cadet members a preliminary training in boat sailing, knotting, and splicing The number of the cadets is limited to 35 at one camp, and, together with officers and instructors, a ship's company of about 45 all told can be housed in twelve bell tents and a large marquee, which serves as a mess Eton, Winchester, Wellington, Gresham, Oundle, St Paul's, and Epsom, to mention a few schools, have been represented in the past years The camp is run on naval lines The hands, as they are termed, are allotted to divisions, and there is keen rivalry between the boats' crews for pride of place A cadet regatta will be held on August 21st, and many well known Norfolk racing yachts will be brought along to compete, when tea will be provided in the marquee for relatives and friends An assistant quartermaster, cook, and mate are engaged to do all the domestic work, so that all the available time may be spent afloat This year we shall be fortunate in having two medical men on the staff, one of whom will always accompany the fleet To those parents and boys who may be interested in this scheme, the honorary secretary, Lieut Colonel F M Tirrupp, "Sandy Bank," Oxted, Surrey, will be pleased to supply particulars on receipt of a post card

NOISE IN HARLEY STREET

DR HORACE HILL writes, Could I be allowed to register a protest against the hideous noise at the north end of Harley Street and ask if anything could be done in the matter? Apart from the impossibility of using any sort of instrument or telephone, the constant din is most bewildering and quite inhibits any concentration

"ANNALS OF MEDICAL HISTORY"

WE are informed by Messrs Baillière Tindall and Cox that the price of a volume of six numbers of the *Annals of Medical History* has been advanced to 50s, instead of 42s, as stated in our review on June 28th (p 1181)

VACANCIES

NOTIFICATIONS of offices vacant in universities medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 38 40 41, 42 43 44 45 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 7

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Prophylaxis in Diphtheria.

E NASSAU (*Deut med Woch*, May 2nd, 1930, p 741) gives his experiences in a children's convalescent home, in which diphtheria was endemic in spite of rigid control of the carriers. There were 19 cases in 1926 and 11 in 1927. From January, 1928, each child on admission received an injection of the diphtheria toxin antitoxin mixture; during the year 8 cases occurred although the numbers in the home rose from 90 to 120. In 1929 each child remaining in the home for more than six weeks received two injections, and, though the number of children had now increased to 135, there were only 3 cases of diphtheria. These 3 and the 8 cases occurring in 1928 were children inoculated either during an influenza epidemic or during the incubation period of measles; it appears therefore, that the inoculation fails if the resources of the body are already being mobilized against another infection. The results obtained are, in the author's opinion, not merely coincidental because the incidence of diphtheria in the neighbourhood was unchanged, several domestic science students in the home (who were not inoculated) developed diphtheria, and did not transmit it to the children with whom they had been in contact immediately beforehand.

2. G RAMON and G I HELIE (*Amer Journ Dis Child*, April, 1930, p 685) present a brief report on the progress made in France in diphtheria prophylaxis with Ramon's anatoxin or toxoid. In 1927 the number of vaccinations was 50,000; in 1928 it had reached 300 000, and during the first six months of 1929 it was 500,000. The standard technique is still the same—namely, an injection of 0·5 c.cm. after three weeks a second injection of 1 c.cm., and two weeks later a third injection of 1·5 c.cm. In from six weeks to two months a negative Schick reaction is obtained in from 95 to 100 per cent. of the cases that showed a positive reaction before vaccination, this immunity is lasting. In cases of three to four years' duration only 1 to 2 per cent. showed reactions to the Schick test. The results from using antidiphtheria serum at the Hôpital Maritime de Berck, an institution for 1,200 patients with tuberculosis of the bone, were: in 1923, four deaths in 34 cases; in 1924, three deaths in 36 cases; and in 1925, five deaths in 67 cases. In 1926 toxoid vaccination was introduced and tried on a great many patients at this hospital; in 1927 and 1928 it was employed for all new patients. In 1928 there were only two very slight cases of diphtheria. The authors remark that even these tuberculous patients give only slight reaction to toxoid.

3. Auricular Fibrillation and the Presystolic Murmur

H. L. WALLACE (*Edinburgh Med Journ*, May 1930, p 303) discusses the occasional presence of a presystolic murmur in patients suffering from auricular fibrillation. It is generally asserted that this murmur ceases to be heard at the onset of fibrillation, since auricular contraction is no longer taking place. The author describes an instance in which the presystolic murmur was retained when this arrhythmia set in. The patient had a four year history of cardiac symptoms, and was shown by electro-cardiography to be fibrillating. The heart was not enlarged, and the rate was 60 to 80 per minute. A presystolic thrill and a loud crescendo presystolic murmur were observed at the apex. This phenomenon has previously been discussed by Eggleston and by Dressler, they assert that the crescendo character of the murmur is an auditory illusion produced by an abrupt loud first sound interrupting the rumbling diastolic murmur, and that such a bruit is never heard when the pulse rate falls below 100, or when the first sound is feeble. Wallace remarks that in his case the murmur occurred only in the latter half of diastole, and with a rate of much less than 100. He suggests that the relaxing ventricle, which exerts its maximal suction effect at the end of diastole is able in the presence of a high degree of stenosis to produce an acceleration of inflowing blood sufficient to give rise to a murmur.

4 The Spinal Cord in Enteric Fever

V. DE LAVERGNE and P. KISSEL (*Presse Méd*, January 22nd, 1930, p 97) state that the spinal cord in enteric fever, like the liver, spleen, and other organs, very frequently presents a reaction to the presence of typhoid bacilli, as is shown by exaggeration of knee jerks, knee and ankle clonus, and the presence of Babinski's sign. In a small number of cases actual myelitis occurs, or there may be an association of neuritis and myelitis.

5 Tularaemia in Canada.

H. D. L. HUDSON (*Canadian Med Assoc Journ*, May, 1930, p 678) reports a case of tularaemia in a miner, believed to be the first case of this disease which has been reported in Canada. Infection followed the skinning and dressing of two wild rabbits, and there was no history of cuts, sores, or glandular involvement. Typical symptoms of tularaemia developed, with a rather diffuse infection of the lungs of a chronic type by an organism of low grade virulence. The blood agglutination test was positive for *B. tularense* in a 1 in 40 dilution. Treatment was purely symptomatic, with the exception of intravenous injections of novarsan, and at the time of reporting the patient was recovering.

6 Gallop Rhythm in Complete Heart block.

J. J. MOZER and P. DUCHOSAL (*Arch des Mal du Cœur*, April, 1930 p 247) refer to the investigation by Gallavardin and by Laubry and Pezzi of the presystolic type of gallop rhythm. These workers established the fact that the presystolic element in each cycle is related to the auricular systole, but is also dependent upon a hypertrophic and hypertonic state of the ventricular wall. Faint regular sounds occurring between the ventricular systoles in complete heart block have been thought to represent auricular systole, and the authors have investigated two such cases by simultaneous registration of the heart sounds and the electro-cardiogram tracing. They find that these extraneous sounds are most apt to occur at the end of the ventricular diastole, and are made up of two elements neither of which synchronizes with the auricular systole. The first element is related to, but follows, the auricular systole, it is probably due to the impact of blood upon the hypotonic ventricular wall. This phenomenon has therefore by analogy been termed "galop du bloc." The second element of the sound is commonly masked by the sound of the succeeding ventricular systole; the authors suggest that it is present in the ordinary presystolic gallop and is then constantly masked. They also attribute it to the abrupt closure of the auriculo ventricular valves by a reflux of blood at the conclusion of the auricular systole.

7 Unsuspected Trichinosis

J. C. WILLETT and C. L. PFAU (*Journ Amer Med Assoc*, April 5th, 1930 p 1060) record an outbreak of 21 cases of trichinosis with one death, in 13 instances the disease resulted from eating improperly cured summer sausage, and in 8 including the fatal case, from eating raw pork sausage. Most of the patients had marked eosinophilia, but one patient in whom eosinophilia was not present died on the sixteenth day, and showed generalized peritonitis at the necropsy. In all of them pronounced symptoms of trichinosis were present before the first case was recognized twenty days after the beginning of the outbreak. In most cases a provisional diagnosis of typhoid fever or malaria had been made.

Surgery.

8. The Significance of Haematuria.

C. S. SWAN (*New England Journ Med*, May 8th, 1930 p 901) records seven cases which emphasize the serious possibilities which may be present in any case of haematuria, whether of small or great degree. He urges the importance of careful microscopic urinalysis, even in the absence of symptoms of genito-urinary pathology, in order that the patient may be referred for differential urological diagnosis if blood is present without any obvious medical and systemic causes to account for it. According to Herman and Eisendrath two-thirds of all cases of haematuria are caused by lesions of the genito-urinary tract, 70 per cent. of these affect the upper and 30 per cent. its lower portion. Swan considers that the term 'essential haematuria' should be dropped as being merely a cloak for diagnostic ignorance. The importance of an early urological examination to establish the diagnosis, and the danger of temporizing with treatment without a complete examination of all possible causes are shown by the cases quoted. The frequency with which exploratory [illegible] and appendicectomy have been performed because of [illegible] plete urinary investigation is borne out by statistics [illegible] Mayo Clinic where it was found that approximately [illegible] of the patients with stone in the ureter had had a previous appendicectomy without relief.

9 Phrenicectomy for Pulmonary Tuberculosis

L W FRANK and O O MILLER (*Annals of Surgery*, May, 1930, p 669) in reviewing 100 cases of pulmonary tuberculosis found that in these selected cases phrenicectomy was a valuable aid to treatment Although 90 per cent of these cases were far advanced, 40 per cent showed improvement, in 8 the sputum became negative for tubercle bacilli, and in 8 the cavities disappeared The method of operation used in nearly every instance was the avulsion of the phrenic nerve, the advantage of this being the removal of the nerve in its entirety, or of enough of it to break the connexions with the accessory phrenic and obtain complete diaphragmatic paralysis, in 44 per cent of cases so treated a better collapse resulted Phrenicectomy is indicated as a preliminary procedure in artificial pneumothorax, when the cavities are thin walled and situated in the infraclavicular region a subsequent pneumothorax may be rendered unnecessary The procedure is also advocated in cases of moderately advanced tuberculosis which have not improved with rest, and for patients clinically well who have a unilateral lesion and positive sputum without definite excavation It should also be tried in all lower lobe tuberculous lesions as a preliminary operation to thoracoplasty, in acute and progressive pulmonary tuberculosis, as an adjuvant in artificial pneumothorax where cavities remain uncollapsed in the presence of a satisfactory pneumothorax, in artificial pneumothorax complicated by a flexible mediastinum, and where pneumothorax is disappearing in consequence of adhesions It was found that good results of phrenicectomy did not depend on the location of the lesions, but on the retractability of the pulmonary tissue Cases with basal and mid lobe lesions profit most, and cavities above the clavicle least, although in the latter, with a marked elevation of the diaphragm, good results are obtained

10 Congenital Fistulae of the Lower Lip

E RUBALTELLI (*Arch Ital di Otol, Rinol e Laringol*, April, 1930, p 141) records his observations on a family which he was able to trace back to 1794 through five generations Of the 70 members of this family 20 died in early life, and 24 had severe congenital developmental deformities of the mouth and lips Of these 24, 11 were affected with fistulae of the lower lip, 11 had double fistulae of the lower lip only, and 2 had cleft palate only The fistulae were different in size, the larger one being situated in the mid line, and the smaller on the right half of the lip They were rounded, with a duct in the centre, the larger fistula measuring 1 to 2 cm and the smaller 1/2 to 1 cm The fistulae were lined with the ordinary mucous membrane of the lip Embryologically, they are due to defective closure of the two inferior maxillary processes Although congenital fistulae of the lower lip do not cause any functional disturbance, the aesthetic deformity calls for operation, especially in the female sex, the procedure merely consists in excising the mucous membrane of the fistulae, and suturing together the margins

11 Trauma and Organic Function

M MARCUS (*Deut Zeit f Chir*, May, 1930, p 158), who records five illustrative cases in patients aged from 12 to 35, states that it is not sufficiently realized that the effects of a shock, especially one applied to the abdomen, extend far beyond the generally recognized area for internal injuries, and may be manifested by disturbances of various organs In the mildest cases these disturbances consist in a transient depression of the functions of the organ in question, in the more severe cases there is an interruption of the function, and in the most severe the organ is partly or completely destroyed The cause of this process is to be found in a reflex or direct involvement of the vasomotor system Marcus adds that on the analogy of cerebral concussion these processes may be described as concussions of the liver, kidney, etc

12 Lipoma of the Stomach

B NEUMANN (*Zentralbl f Chir*, May 10th, 1930, p 1154), who records a personal case, illustrates the rarity of benign tumours of the stomach by the fact that Gutierrez found only 27 examples (none of which was a lipoma) among 2,168 gastric tumours which had been operated on at the Mayo Clinic Tilger, on the other hand, found two lipomas among fourteen connective tissue tumours in 3,500 necropsies The difference in these two findings is explained by the fact that benign gastric tumours are frequently not diagnosed during life owing to the dearth of symptoms Subserous tumours only become obvious when they have grown to such a size as to cause symptoms of compression, or haemorrhage, in such cases a diagnosis can be made by x ray examination Submucous tumours give rise to symptoms earlier, when situated in the pre-pyloric antrum they may produce obstruction They may also lead to ulceration of the mucous membrane, and attract attention by the haemorrhage so caused The diagnosis is most difficult when the tumour is situated in the wall of the stomach Only three previous cases of gastric lipoma have been recorded, by H Fischer, Spitzmuller, and Weicker respectively Neumann's patient was a woman, aged 65, in whom a diagnosis of carcinoma of the stomach was made before the operation Laparotomy revealed a lipoma measuring 15 by 4 cm in the anterior wall of the stomach, it was situated between the muscularis mucosae and muscular coats Resection of the stomach was performed and the patient made an uneventful recovery

Therapeutics.

13 Intracardiac Injections of Adrenaline in Severe Syncope

P. MATHIEU (*Bull et Mém Soc Nat de Chir*, May 17th, 1930, p 591) discusses two cases reported by D Percy in which severe attacks of syncope were cured by the intracardiac injection of adrenaline One of the patients, who was aged 19, collapsed under ethyl chloride anaesthesia just before an operation for paraphimosis was about to commence The patient became black, the heart beat could no longer be heard, and respiration stopped. In spite of the fact that death seemed to have occurred, adrenaline was injected into the heart, and, shortly after, the first signs of recovery were apparent, so that the operation was eventually performed The second patient was aged 69, and had fractured his left femur Spinal anaesthesia was induced, but the patient collapsed before any operative steps were taken In his case also restoration followed the injection of adrenaline, but it was an hour before the pulse became regular Mathieu remarks that these two cases emphasize the importance of intracardiac adrenaline injections in cases of syncope, particularly in view of the fact that there are no unpleasant sequels He comments on the fact in the second case that the transference of the patient in a stretcher to the operation table was apparently sufficient to induce collapse, there was also a long period of coma before recovery supervened In both cases 1 c cm of 1 in 1,000 adrenaline was injected into the heart

14 Prolonged Iodine Treatment of Exophthalmic Goitre

THOUGH the prolonged treatment of exophthalmic goitre with iodine alone has come to be regarded as a futile, if not a dangerous, procedure, cases have been reported of favourable results following the employment of this method W O THOMPSON, PHEBE K. THOMPSON, A G BRAILEY, and A C COHEN (*Arch Int Med*, April, 1930, p 481) review these cases, and record observations made during the last three years at the Massachusetts General Hospital on 24 cases (14 mild and 10 severe or moderately so), most of whom were followed closely with basal metabolism determinations while under going prolonged treatment with iodine alone Iodine was used in the form of Lugol's solution Some observers believe that small doses are less harmful during prolonged medication than are large ones Though in this series the customary dose has been comparatively small—namely, 1 drop of the solution (about 6 mg of iodine) daily—in instances in which it was administered in much larger doses, even as much as 90 drops daily, there was no proof that the increase had an adverse effect The patients were treated with iodine alone, either continuously or intermittently, for periods of from one and a half months to three years The period was a year or more in 13 cases With three exceptions (all unsatisfactory responses to iodine) the patients continued their work during the period of observation, thus eliminating the effect of rest In 9 of the mild cases the results were satisfactory the thyrotoxicosis being either completely or almost entirely kept under control and the basal metabolism kept at a normal level, in 3 the results were fairly satisfactory, inasmuch as definite improvement was shown despite tardiness or fluctuations in the response, and in only 2 were the results unsatisfactory, though the disease did not become worse In the 10 severe or moderately severe cases the results were satisfactory in only one, 4 showed no permanent improvement, and in 5 the disease became worse From these observations the authors conclude that patients with severe or moderately severe exophthalmic goitre rarely show more than temporary improvement during the prolonged administration of iodine, and frequently the disease becomes worse If the disease is mild, however, patients often respond satisfactorily, and in some cases it terminates The response appears to be determined more by the manner in which the disease is progressing spontaneously than by the iodine itself In the cases showing satisfactory results iodine may have merely held the disease in check, but, even so, it would appear to be valuable in the treatment of mild exophthalmic goitre

15 Vaccine Therapy of Urinary Infections

T CIMINO (*Arch f Urol* B 1 2 H ft 5 1930 p 3 0) records the results of his treatment in over 500 cases of urinary infections other than gonorrhœa and tuberculosis The method consists in the aseptic collection (by catheter) of a small quantity of the patient's urine this is brought momentarily to boiling point three or four times over a flame and allowed to cool A few drops (no more than five) are injected subcutaneously the first day about 0 5 c cm on the second day then 1 to 3 c cm the full course consisting of about ten injections It is claimed that the urine forms an ideal antigen and combines vaccine with protein therapy Of the acute cases (mostly *B coli* infections) 86 per cent were cured and 9 per cent improved of the subacute cases 57 per cent were cured and 31 per cent improved of the chronic cases only 7 per cent were cured and 16 per cent improved The local and general reaction following injections is said to be slight as a rule, and the procedure to be without danger

Neurology and Psychology

16. Spontaneous Meningeal Haemorrhage

T H LAMB (*Journ Lab and Clin Med* March 1930 p 530) considers that his experience with seven proved cases (which are here reported) and two probable ones of spontaneous meningeal haemorrhage in the course of years indicates that the condition is overlooked more frequently than it is diagnosed This condition must be differentiated more especially from subdural haematoma in its various stages of development and from the similar if not identical condition pseudo-membranous pachymeningitis haemorrhagica interna The clinical syndrome of spontaneous meningeal haemorrhage is the picture of severe meningeal irritation with an abrupt onset and without obvious cause prompt relief follows removal of the spinal fluid which contains blood The symptomatology of chronic subdural haemorrhage is extremely variable usually there is a history of injury a gradual onset and a final stage of hemiparesis The symptoms of intracerebral or capsular haemorrhage are well known those of spontaneous meningeal haemorrhage as revealed by the seven cases here recorded are as follows The patients, previously well were engaged in their usual occupations and a history of cranial trauma was absent The first symptom was a sudden, sharp excruciating pain in the head which was soon followed by symptoms of meningeal irritation with active delirium and partial loss of consciousness As the disease progressed the great pain continued with restlessness and cerebral impairment varying from delirium to profound coma The pupils were dilated equal and regular, they reacted to light and accommodation A definite but not marked general rigidity of the body and extremities was present but no paralysis As a group, the superficial and deep reflexes were generally diminished and influenced by the mental state The most important single finding was a cerebro-spinal fluid uniformly mixed with blood, and under increased pressure, with a slight proportional increase of leucocytes and no tendency to clotting On standing the cells settle, making up as much as one twentieth the volume of the mixture Early in the attack the supernatant fluid is colourless, but xanthochromia increases as the red cells diminish and show degeneration The presence of such a fluid is the cardinal sign of spontaneous meningeal haemorrhage In five cases where drainage of the subarachnoid fluid (lumbar puncture) was instituted early and repeated, prompt improvement and recovery followed In two cases where drainage was delayed death occurred within twenty four and thirty six hours respectively

17 Decerebrate Rigidity

DECEREBRATE rigidity was first described by Sherrington in 1896 in animals, and it was not until 1919-20 that this syndrome was first recognized in man Since that date numerous cases illustrating the phenomenon of decerebration have been reported S H EPSTEIN and P I YAKOVLEV (*Journ Neurol and Psychopathol*, April, 1930 p 295) record another case which revealed the clinical condition of decerebrate rigidity with the tonic neck reflexes of Magnus and de Kleijn, extensor rigidity, pseudo-affective reactions (hyperacusis), and tonic fits From the history and physical findings the case apparently was one of cerebral infantile tetraplegia, either of congenital origin or due to a lesion occurring during or immediately after birth A male child was admitted to hospital at the age of 2½ years and died in the same institution about six years later The main clinical features are discussed under four headings attitude and postural reactions muscle tonus fits and general and local motor reactions The attitude was one of permanent extension with retraction of the head, and, in addition the tonic neck reflexes of Magnus and de Kleijn was present These exhibited remarkable constancy they could be readily induced by passive movements of the head and were often reproduced by spontaneous movements of the head Since birth the patient had had fits not apparently all alike but of two types The first type consisted of a tonic and clonic phase with loss of consciousness and the second simply of the tonic phase without any obvious loss of consciousness The muscle tonus was increased and was equally distributed in the flexors and extensors The reaction of the antagonist muscles was exaggerated and shortening and lengthening reactions were present The pattern exhibited both general and local motor reactions when various external stimuli were applied Pathological findings in the central nervous system were microcephaly and microgyria cerebral aplasia with absence of the corpus callosum aplasia of the cerebellum medulla and basal ganglia degeneration of the red nucleus thalamus and cortico-spinal tract and diffuse gliosis

18 The Sedimentation Rate in Psychoses.

J L R CORDELA (*Arch de med cir y esp* April 19th 1930 p 516) has made a study of the sedimentation rate according to the method of Fahræus in cases of general paralysis alcoholism, epilepsy and schizophrenia and comes to the following conclusions The sedimentation rate has only a limited value in the study of psychoses, and considerable care must be taken in drawing too absolute or premature conclusions therefrom Its diagnostic value is slight being limited to a presumptive sign of organic change or of toxic phenomena The close relation existing in other morbid processes between the degree of acceleration and the intensity of the lesions is found also in organic mental diseases. The sedimentation rate may therefore form a valuable guide as regards the course and possibilities of the treatment of general paralysis Psychomotor restlessness forms a transient cause of the acceleration of the sedimentation of the red corpuscles The number of the leucocytes is one of the factors determining the sedimentation rate as is shown by the delay in the rate observed in all those processes in which there is a transient leucopenia (spontaneous or provoked epileptic attacks oculo cardiac reflex or lumbar puncture

19 Schizophrenic Reactions following Influenza.

G P KAMMAN (*Journ Amer Med Assoc*, April 26 h 1930 p 1286) who records four illustrative cases in patients aged from 17 to 31 distinguishes cases of dementia præcox which terminate in permanent dementia from borderline cases presenting similar symptoms to the latter the term schizophrenic reactions has been applied such cases differing from dementia præcox by their favourable termination Kammau points out that a schizophrenic reaction is not a specific entity due to a single causative agent but may be the sequel of a number of endogenous and exogenous causes including influenza The influenzal organism frequently produces a high degree of neuro-toxicity, and besides evoking a schizophrenic reaction may originate other mental states such as acute manias and depressions The schizophrenic reaction is the most frequent mental effect of influenza and its prognosis is much more favourable than that of true dementia præcox

Obstetrics and Gynaecology.

20 Prognosis in Uterine Cancer

W P HEALY (*New York State Journ of Med*, February 15th, 1930, p 191) emphasizes the extreme importance of early diagnosis in uterine cancer Broders of the Mayo Clinic has distinguished four groups by pathological criteria Group I cases contain highly differentiated adult epidermoid cells Group IV comprises cellular tumours with undifferentiated embryonic and anaplastic cells associated with rapid lymphatic metastasis, Groups II and III are intermediate Statistics show only 9.5 per cent of five year cures in Group IV cases treated by hysterectomy while radiation therapy results in 66 per cent The same grouping in cancer of the body of the uterus reveals that there were no five-year cures in Group IV cases treated by hysterectomy though 50 per cent cure resulted from radiation therapy The average operative mortality of Wertheim's operation being 15 per cent., advanced cases are regarded as being always unsuitable for hysterectomy In Healy's series 23 per cent of patients with advanced disease were alive five years after radiation The author adds that he has known no case of survival for five years after treatment for uterine cancer in any patient under the age of 30

21 **Rapid Manual Dilatation under Spinal Anaesthesia**

A PISTUDDI (*Ann di Ostet e Ginecol*, March, 1930, p 224) describes the trial in eleven cases of rapid manual dilatation of the cervix by the method of Delmas after the induction of spinal anaesthesia The cervix was undilated in one case, dilated to three centimetres in another, and in the rest admitted one finger without being "thinned out" The method failed in one case, which was terminated by vaginal Caesarean section, and in three cases there were difficulties in attaining full dilatation It was nevertheless easy with the method rapidly to attain two to three fingers' dilatation of the unmodified cervix, or in patients in whom labour was moderately advanced to obtain quickly a sufficient dilatation to allow of introduction of the hand within the uterus, followed by version and extraction In eleven cases there were three lacerations of the cervix and four of the perineum, in one case there was considerable bleeding before the third stage was completed It is concluded that the method of Delmas is far from removing the difficulties of rapid delivery in the uterus not yet modified by early labour pains, but that future experience may prove it to have considerable utility in certain cases of placenta praevia.

22. ACCORDING to GONNET (*Bull Soc d'Obstet et de Gynécol de Paris*, February, 1930, p 124) the procedure suggested by Delmas does not give uniform results Although he has known it to succeed perfectly in certain cases before labour, even in primiparae, he finds that cases of prolonged labour with uterine contracture and resistant cervix are refractory to dilatation under spinal anaesthesia In these cases digital dilatation under chloroform narcosis is preferable, but in general as well as in spinal anaesthesia it is wise to perform vaginal hysterotomy if the cervix proves resistant

23 LEARVIER (*ibid*, p 126) describes trial of this method in three cases—eclampsia, shoulder presentation, and placenta praevia respectively In the first patient, a primipara, who was found in coma at term with a thin, minimally dilated cervix, complete dilatation was obtained in four minutes, and a living infant weighing 6 lb was extracted after version, a cervical tear reached the fornix In the second patient, a primipara in labour at the eighth month, dilatation was difficult and only obtained at the expense of a tear of the vaginal cul de sac, delivery of the after coming head was impeded by cervical retraction, and the child was stillborn In the third patient the presentation was a breech, there was procidentia of the cord, and there had been considerable haemorrhage The mother and child ultimately did well, but a tear of the vaginal vault almost penetrated the abdominal cavity

24 A GINGLINGER (*ibid*, p 142) describes seven trials of this method with three failures He concludes that it gives good results when the cervix has to some extent been effaced initially, unimportant tears, however, may be produced When the cervix is still long the procedure is liable to fail, and may cause serious cervical lacer the dilatation obtained is sleeve like and unphysiological The method of Delmas is only indicated in cases of maternal suffering, and the decision to try it calls for considerable judgment It is specially applicable in cases of prolapse of the cord, placenta praevia in multiparae, and breech presentations in elderly primiparae

25 **Intrauterine Charcoal Treatment in Gynaecology**

THE results reported by Benthin and Geller led H NAHMMACHER (*Surg, Gynecol and Obstet*, May, 1930, p 873) to employ the intrauterine administration of charcoal in gynaecological cases, and he has obtained similarly favourable results The most important quality of medicinal charcoal is its high degree of adsorptive power, which it owes to its porous structure and consequent great surface energy, thus being enabled to fix other substances In addition to this property, the astringent action of charcoal is not inconsiderable The author remarks that the preparations of charcoal employed must be of high standard, their suitability depends not on their source (animal or vegetable), but solely on the method of treatment of the charcoal The use of charcoal, in the form of granulated pencils, is indicated in cases of infected abortion, before or after clearing out the products, according to the condition of the patient, in cases of puerperal endometritis (not before the seventh day of the puerperium), and, prophylactically, in cases of Caesarean section after rupture of the membranes The technique of this therapy, which is very simple, is described Nahmmacher states that the reported results of charcoal treatment are so favourable that they cannot be rejected Its intrauterine application is completely free from danger, the medicament is very cheap, and the period of illness is greatly shortened The symptoms are influenced at once, and never for the worse, the body responds with an immediate improvement in the general condition and in the local process, with a fall in the temperature and pulse rate A few remarks on the value of intravenous charcoal therapy are appended

Pathology.

26 **Lesions Due to the Toxin of Clostridium welchii**

M WEINBERG and N COMBIESCO (*C R Soc de Biologie*, April 4th, 1930, p 1091) injected a series of 16 guinea pigs, of 350 to 400 grams in weight, with doses of 2 5 to 12 5 mg of dried toxin of *Cl welchii*, this was diluted in distilled water and injected intravenously The lesions were numerous and diverse All the animals without exception had one or more bouts of haemoglobinuria, often followed by haematuria, and all died within ten to twenty four hours The lesions seen at necropsy, and those rendered evident by histological examination of the tissues, could be ascribed to the action of the haemolytic toxin, to the non haemolytic toxin, or to the toxin that causes a rise in blood pressure The haemolysin gave rise to a marked haemoglobinuria, and led to the deposition of pigment in the kidneys, spleen, liver, and lungs The non haemolytic toxin was responsible for focal areas of necrosis in the kidney and liver In the kidney the straight or convoluted tubules in the medullary region were most frequently affected In the liver the necrotic areas were larger, and were visible to the naked eye as greyish spots, which often extended from the capsule to the interior for a distance of 2 cm The same toxin was also responsible for the gelatinous oedema which was apparent in the axillary and inguinal subcutaneous tissue, and in the connective tissue of the mesentery and the retroperitoneal region The toxin that causes a rise in blood pressure led to the occurrence of haemorrhages in several organs Besides the kidney, haemorrhages were very severe in the spleen, the tissue of which was often completely disintegrated by the blood They occurred in the liver and in the lungs, where the blood ruptured the alveoli and passed into the bronchi and trachea In the suprarenals they were found most frequently in the zona fasciculata Sometimes they occurred in the mucosa of the stomach and uterus The muscles were rarely affected The authors regard these experiments on animals as supporting the view that haemoglobinuria, haematuria, haemoptysis, and intestinal and uterine haemorrhages observed in patients infected with *Cl welchii* are due to the toxins of this organism.

27 **Transplacental Passage of Tuberculosis**

BRINDEAU, DE BEAUFOND, P CARTIER, and POUGIN (*Bull. de l'Acad de Med*, March 25th, 1930, p 300) report a case in which a woman aged 29, 4½ months pregnant, was operated on for the removal of a tuberculous kidney She died of shock forty-eight hours later At the necropsy none of the thoracic or abdominal organs showed macroscopical signs of tuberculosis, but 20 c cm of amniotic fluid was removed aseptically through the wall of the uterus and centrifugalized, the filtrate was mixed with sterile physiological saline solution and 3 c cm. was injected into two guinea pigs The uterus was opened, and the viscera of the foetus were [illegible] and emulsified in sterile normal saline solution, emulsion was injected into a guinea pig, and 3 c cm of an extract of the placenta in sterile normal saline solution which had been injected into another guinea pig The guinea pigs with failing kidneys and the visceral and placental emulsions died received the amniotic fluid, one died from tuberculosis, the other survived large tuberculous lesions Of the two which

28. **The [illegible] Reducing Action of Br abortus and Br melitensis**

H HABS (*Zeitschr f Bakt*, March 28th, 1930, p 89) has tested the reducing power of *Br melitensis* and *Br abortus* added to a two dilution of a few strains of *Br abortus* and was then covered number of different dyes The dye was The final concentration of the organism, the broth 1 in 10,000 and 1 in 4th a layer of paraffin and incubated coloured with dye in of the dye was generally between happened, the medium 000 A control tube of sterile medium results showed that, put up, in case, as not infrequently reducing power Of itself had a reducing action The four were strongly re the whole, these organisms had little dine blue, and creasy ly one different dyes tested only powers of *Br abortus* d—thionin, methylene blue, tolui- 6 No difference in the reducing *Br melitensis* was observed

Sept. 10th, 1929.

Dear Sirs,

I have prescribed Agotan* Tablets, grains $7\frac{1}{2}$, to an elderly lady suffering from Rheumatoid Arthritis of the hip and knee joint.

She has derived great benefit from the treatment and her pains have been much relieved.

————, M.B.

* *This refers to Howards' Agotan Tablets Agotan is official in "The British Pharmaceutical Codex, 1923"*

According to eminent Medical Men, Agotan owes its remarkable success in the treatment of Gout, Sciatica, Rheumatism, Lumbago, Neuritis Arthritis, etc, to the very powerful elimination of Uric Acid from the blood, thus preventing its deposition in joints, etc

Obtainable through any wholesale house in bottles of 25 and 50 Tablets of $7\frac{1}{2}$ grains each, or in Powder, also in Ointment form for local application

Samples and full particulars to Medical Men from the manufacturers

HOWARDS & SONS LTD (Est 1797), Ilford, London

BRITISH SPAS are best

and membership *of the* British Spas Federation is a guaiantee of efficiency.

AT British Spas treatment is only given (except in a few minor cases) upon medical prescription

At British Spas the Staffs are educated and properly trained, and, in some cases, medically trained and medically certificated

Equipment and administration are thoroughly up-to-date and scientific Every new treatment is tested and reported upon before being adopted

British Spas are also remarkably fortunate as regards situation, scenic beauty, and pure air These factors, combined with the social amenities of a home town, aid the cure considerably

A New Medical Handbook is being published, specially prepared for the use of the medical profession A copy will gladly be sent you if you will write to the Hon Secretary, Box I, British Spas Federation Thermal Baths, Buxton, or to the Managers of any of the Spas here mentioned

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY (D M R & E)

The Course of study for the Diploma which is open only to duly qualified medical men and women begins on October 1st, 1930, and occupies nine months

The first three months may be spent either in Cambridge (where the Physics is done in the Cavendish Laboratory and the Radiology and Electrology in the Department of Radiology) or in London (where the Physics is done at the Middlesex Hospital or King's College and the Radiology and Electrology is taught at the British Institute of Radiology) These Courses run concurrently in Cambridge and London

The second three months must be spent in London where lectures are given at the British Institute of Radiology and are combined with clinical instruction in the large teaching hospitals

The third three months may be spent in recognized hospitals in London or elsewhere the student acting as clinical assistant or in similar capacity

The examinations consist of three parts viz
1 Physics with examinations in January and April
2 Radiology and Electrology, with examinations in April and July
3 The presentation of a thesis or exercise which is entirely the candidate's own work and is intended to show that he has had practical experience of the subjects

Further information as to the Courses may be obtained from
G SELAS M A Secretary for the Diploma and Lecturer in Physics as applied to Medical Radiology Cavendish Laboratory Cambridge

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below

Candidates must be British subjects under 32 years of age at the time of application and must be registered under the Medical Acts in force in Great Britain and Northern Ireland

CAREERS

The Indian Medical Service offers wide opportunities of medical experience including clinical preventive specialist and research work At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army Promotion is on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General An officer may apply after two years Indian service to have his name registered for transfer to the civil side from which appointments are made to Civil Surgeoncies which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes to specialist (for example public health and bacteriological) services to research posts and to professorships at the Medical Schools

PAY

The monthly rates of pay for European officers in the Service who have a non Asiatic domicile are as follows

Rank	Service in Rank	Rate of Pay	Overseas Pay	Year of Total Service
1	2	3	4	5
		£	£	
Lieut		411	150	1st
			150	2nd
			150	3rd
Capt	(i) During first 3 years service as Captain	600	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs service as Captain	700	£25	7th
			£25	8th
			£25	9th
—	(iii) With more than 6 years service as Captain	800	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years service as Major ..	900		
	(ii) With more than 3 and less than 6 years service as Major	1100		
	(iii) With more than 6 years service as Major	1250		
Lieut Col	(i) Until completion of 23 years total service ..	1500	£30	13th and over
	(ii) During 24th and 25th years service	1600		
	(iii) After completion of 25 years total service	1 00		
	(iv) When selected for increased pay ..	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service

ANTEDATES IN COMMISSION

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer may be counted as service for increments of pay promotion retirement and retired pay but not for gratuity

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions Past service in certain hospital appointments may also render candidates eligible for an antedate of one year Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year The maximum period of antedate secondment or antedate and secondment combined admissible under this paragraph is limited to one year

OUTFIT ALLOWANCE

Officers on appointment will receive an outfit allowance of £50

PRIVATE PRACTICE

With the exception of Administrative Officers military or civil and officers holding certain special appointments officers are not debarred from taking private practice so long as it does not interfere with their proper duties

PENSIONS

The rates of pension are as follow.	Per annum
	£
After 17 years service for pension	410
18	430
19	460
20	500
21 ..	540
22	580
23	620
24	660
25	700
26	750
27	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent in all the revision being undertaken triennially With effect from July 1st 1927 a reduction of 4½ per cent has been made on this account from the amounts shown

There are additional pensions ranging from £65 to £300 per annum for officers who have held administrative appointments

PASSAGES

An officer on appointment is provided with a free passage to India The wives and families of officers who are married prior to the date of the officers embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Millbank lasting approximately six months prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department India Office London, S.W.1 The Selection Committee will meet at the India Office in July and the selected candidates will be required to join a course of instruction commencing early in August, 1930 Applications should be submitted as soon as possible

EAST AFRICAN MEDICAL SERVICE.

VACANCIES at present exist for MEDICAL OFFICERS in the EAST AFRICAN MEDICAL SERVICE

Qualifications—Candidates must be British subjects of European parentage and under 35 years of age They must possess a double qualification and be on the British Medical Register Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc

Salary—£600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by £40 to £920 per annum

Quarters—Free quarters are provided or an allowance is given in lieu

Passages—Free first-class passages are provided both on first appointment and when proceeding on or returning from leave A married officer will be granted an allowance towards the cost of his family s passage once each way in respect of each tour of service

Terms of Appointment—The appointments are pensionable subject to a probationary period of two years in the first instance

Length of Tour of Service—The normal tour of service is 20 to 30 months, after which leave is granted, with full salary, for 2½ to 3½ days, according to the districts in which the officer has served, for each month of service, plus the period of the voyage to England If the officer is returning to East Africa for further service, he receives a further similar amount of leave, plus the period of the voyage to East Africa

Course of Instruction in Tropical Medicine—Selected candidates will normally be required to undergo a course of instruction in Tropical Medicine and Hygiene before proceeding overseas

Duties—Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research

Further particulars and forms of application may be obtained on application, in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S W 1

New Zealand.

29. MANCHESTER.—Residential.

[REGISTERED AS A NEWSPAPER

AVENZOAR
(1075 1162)

Spanish physician One of the few of his time who had the courage to tilt against Galenism

CALLED "The Wise and Illustrious," Avenzoar realized that palatability in the medicines he was using was a very desirable attribute In the Latin translation of his treatise, "Al Teisir," it is recorded that when the Caliph needed a purgative, Avenzoar conceived the idea of spraying a grape vine with a purgative solution, and supplying his royal patient with the grapes thus medicated

Its agreeable taste makes Agarol Brand Compound, the modern mineral oil emulsion with phenolphthalein, acceptable to the most fastidious patient Because it softens the intestinal contents and *gently stimulates* the peristaltic action, Agarol Brand Compound accomplishes the two most desirable results in the treatment of constipation

Liberal trial quantities at disposal of physicians upon request

Taka-Diastase

PARKE, DAVIS & Co, introduced Taka-Diastase to the medical profession more than a quarter of a century ago, and it was not long before it came to be recognised as the standard remedy for so-called amylaceous dyspepsia

Without question, Taka-Diastase is the most powerful of all amylolytic agents of vegetable origin It is standardised to render soluble three hundred times its weight of dry starch in ten minutes, the starch being transformed to dextrins, maltose and dextrose

Taka-Diastase is also an active proteolytic and, further, acts in neutral, slightly alkaline or slightly acid media Whilst a very active therapeutic agent, Taka-Diastase is perfectly harmless Being tasteless, it is freely taken by children and fastidious patients

Supplied as powder, tablets or liquid Tablets are also available containing Taka-Diastase with pepsin, pancreatin or strychnine It may also be obtained as an elixir, with bismuth, nux vomica and hydrocyanic acid Further particulars will be sent to any member of the medical profession on request

DIETETIC VALUE OF

RYVITA

CRISPBREAD

RYVITA
1930 TALKS
No 5

Ryvita is made of pure crushed whole-grain rye and is baked to a delicious crispness in a way that preserves all the rich nutriment of the grain, while making Ryvita particularly appetising

The great ease of digestion of Ryvita is due both to its physical and to its chemical nature Its crispness and dryness necessitate proper mastication, and ensure thorough saturation of the bolus with saliva Its high percentage of soluble carbohydrates (43%) greatly lightens the burden of starch digestion

The laxative action of Ryvita is also partly physical, and partly chemical—due to the roughage of the bran and the high percentage of phytates

Ryvita is body-building—not fat-forming It is a complete cereal food, giving a well-balanced protein-carbohydrate ratio, It is also rich in the essential body-building salts of Iron, Phosphorus, and Calcium

Ryvita is rich in Vitamin B, the deficiency of which in white flour and white bread is causing concern in medical circles

Where Ryvita is indicated it is usual to suggest that the patient begin by eating two or three slices with one meal each day

We shall be very pleased to send Free Samples and full particulars to any Interested Member of the Profession

THE RYVITA COMPANY LTD.,
640 RYVITA HOUSE, 96 SOUTHWARK STREET, S E 1

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes *"Ardente' is a godsend to me"*, without "ARDENTE" he is, to all intents and purposes, "stone" deaf, with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised Doctors whose work lies amongst the deaf prefer to prescribe ARDENTE because they know that ARDENTE is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what ARDENTE' service stands for to the deaf Many doctors who are deaf use ARDENTE'

ARDENTE is entirely different and uncopyable and succeeds in widely differing cases A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus Minutely adjusted to the requirements of the case for young middle aged or old and so sensitive as to have the desired effect even in middle ear and nerve cases bringing into action and stimulating the auditory system enabling it to function naturally and saving atrophy "ARDENTE" can be used or not at will, and is sold under guarantee

ARDENTE" is the choice of Doctor and patient—only after test and hearing or from prescription or particulars is ARDENTE' fitted toned, tried, adjusted, supplied, and serviced

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation

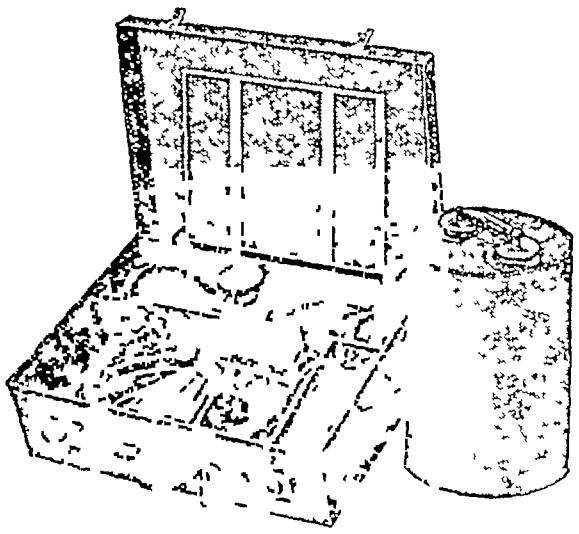
IN THE CONSULTING-ROOM—



Doctors everywhere praise the "METALIX-PORTABLE."

Almost daily the number of general practitioners using the "METALIX-PORTABLE" grows larger—once they have acquired the outfit, a wider sphere of usefulness opens up to them—they become "METALIX-PORTABLE" enthusiasts

In consulting room or patient's home, the "METALIX-PORTABLE" will produce radiograms of remarkable definition which greatly facilitates accurate interpretation The doctor need possess no electrical knowledge—there are no complicated controls—no element of danger

Consider for a moment the possibilities in your practice Ask us to carry out a demonstration or to send descriptive literature

THIS NEW *FLEXIBLE* SUPPORT

IS APPROVED BY LEADING SURGICAL OPINION

FRONT VIEW

At the front of the belt the thin tricot of great strength can be extended to the required depth so that a gentle pressure is exerted on the full area of the abdomen

Pads can of course be attached if necessary

Being Pliable, it Exerts a Firm yet Natural Compression without Restriction

THE Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who not only prescribe it for their men and women patients, but also adopt it for their own personal use

BACK VIEW

The tough five horizontal elastic of this special tricot can be regulated to the required tension Thus its lifting and *massaging powers are easily* controlled As the abdomen resumes its normal conformation further adjustments can be made by means of the back lacing.

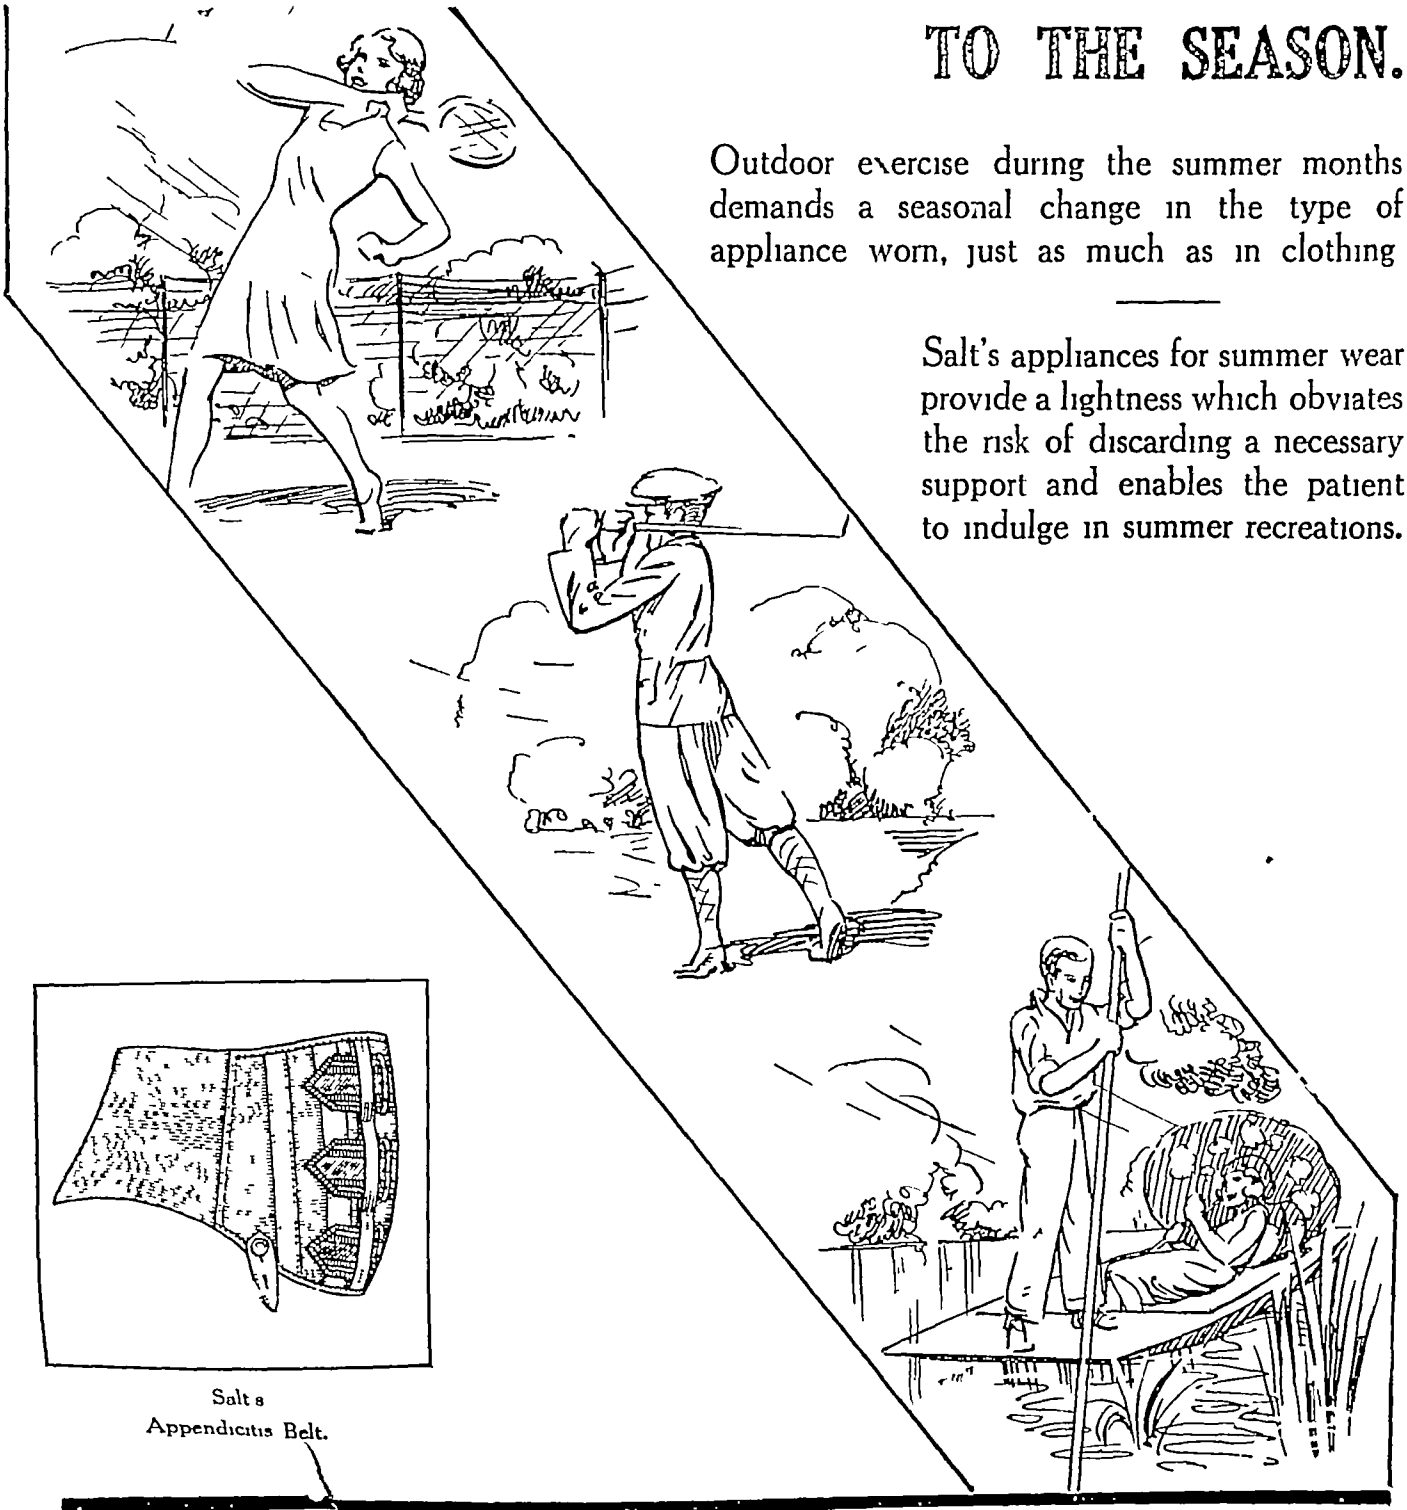
THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post operation wear *without employing any rigid components* Thus it allows complete *freedom in movement* and breathing Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation Recommended for post-operation wear, in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis, Cesarotomy, etc.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards Standard depth 11 inches *Prices:* Standard Model in thread and elastic, 2½ guineas In pure silk and elastic, 5 guineas Post free in United Kingdom

The Linia Belt



is on sale only at

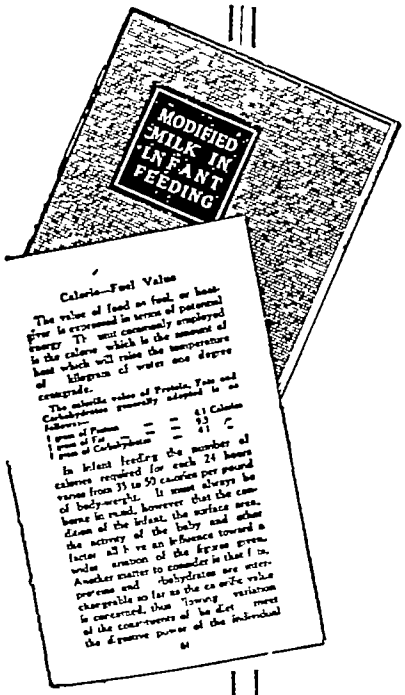
Non-Caustic
Palatable



H K MULFORD
COMPANY LTD.
Regent Arcade House,
252, Regent Street,
London, W 1

CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated For the first time the well-known protectives and antacids—bismuth, magnesia and lime—are supplied as a suspension of particles of colloidal dimensions

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth magnesium, and calcium

CREMO-CARBONATES is a soothing antacid, corrective, and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices

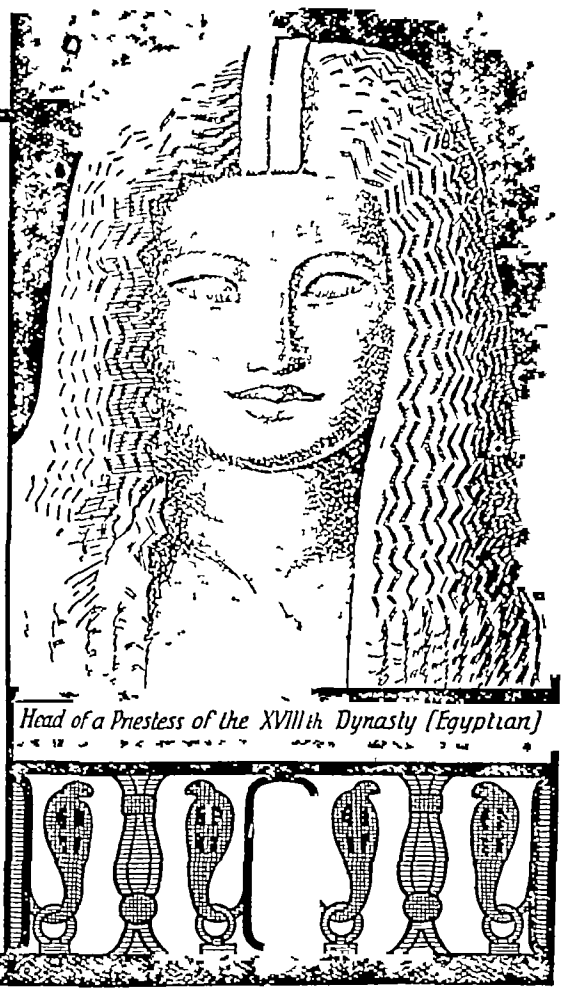
MELLIN'S FOOD Ltd., LONDON, S.E 15

OVALTINE

FOR THE AGED

"Ovaltine" is delicious sustenance for old people It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions "Ovaltine provides complete nourishment in easily assimilable form Its use greatly increases the nourishing value of other foods The digestibility of milk, for instance, so largely used in old age, is increased two-fold by adding "Ovaltine to it, while the starch in the cereals is converted into easily assimilated malt sugar by the enzyme diastase which "Ovaltine ' contains in abundance



"Ovaltine is purin-free Its use, therefore, neither aggravates, nor favours the accumulation of uric acid in the system, nor leads to kidney disorder or gout The tendency to constipation, so common in old age, is avoided by the use of "Ovaltine

"Ovaltine' replaces to great advantage the usual meal-time beverages, tea and coffee, which are valueless as sources of nourishment and often contraindicated in senility

GAS

Gastric and Intestinal

The Medical Profession are acutely aware of the number of deaths that can be directly ascribed to mechanical pressure of gas in stomach or bowel, and how many cases of *morbus cordis*, asthma and pelvic trouble are complicated by this physical cause alone.

Faulty diet and oral sepsis lead to faulty metabolism, fermentation, and excessive formation of toxins from multiplying gastro-intestinal flora.

This generalisation is a cold unwelcome truth to the doctor called in to relieve severe symptoms of wind round a weak heart, or general abdominal distension who knows that flatulence and alvine meteorisms can only be effectually controlled by limitation of the gas-forming bacteria

A potent non-toxic bactericide is the only adequately permanent assistance on which he can rely, and the efficiency of Dimol in gastro-intestinal fermentations and all other disabilities of bacterial origin secures him in that reliance

Clinical reports together with a brochure dealing with the pathological significance of the intestinal toxaemias will be sent to any medical man on application to the

STARCH-REDUCED — NOT STARCH FREE

RECENT advances in diet therapy have led to the complete reversal of earlier methods—the almost total exclusion of starch from the dietary of diabetic patients is now recognised as fundamentally wrong. The modern dietetic treatment of diabetes demands that bread and other farinaceous foods shall contain carbohydrates up to, but not in excess of, the ascertained degree of tolerance, whether insulin is used or not. Indeed, in all disorders of the alimentary tract, from whatever cause an adjustment of the protein and carbohydrate on defined and accurate lines is admittedly essential.

Energen starch reduced and protein increased products enable the physician to prescribe definite proportions of carbohydrate, protein, and fat to patients suffering from Indigestion, Rheumatism, Obesity, and similar complaints, the composition in grams and the total calorie value being stated on every packet.

Dietetic monographs, diet tables for diabetics—revised in accordance with the recent report on the Carbohydrate Content of Foods prepared for the Medical Research Council (Privy Council) by McCance and Lawrence—diet tables for obesity and light diets, and samples, will gladly be furnished to Members of the Medical Profession.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio

The vitamins of its constituents are unimpaired by the Horlick process

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage Most children like the natural flavour of malt and will drink Horlick's with pleasure And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/- Also in tablets

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co , Ltd , Slough, Bucks

The Best Substitute for Mother's Milk

The ease of digestion of Almata ensures healthy and regular bowel action Its content of malto-dextrins and fruit juice renders it very slightly laxative in contradistinction to most other infant foods, which generally cause constipation

MONSOL *in* MIDWIFERY

An authority on the subject has expressed the considered opinion that the use of Monsol in midwifery would reduce the incidence of Puerperal Sepsis by fully 90 per cent

Bacteriologists and Clinicians have proved repeatedly that Monsol has a selective action on Streptococci—an action ten times greater than lysol (which cannot destroy these germs except at a concentration liable to injure the tissues)

Outstanding features of Monsol are

1 A high germicidal power against the organisms that cause sepsis

2 A bland and emollient action—non irritating to the tissues and mucous membranes at therapeutic concentrations

3 Low toxicity (One sixth as poisonous as lysol)

4 Great powers of penetration reaching deep-seated inflammation

Many Hospitals Nursing Homes and Lying in Institutions are now specifying the use of Monsol in all maternity cases In addition to reducing the risk of infection Monsol leaves the hand and skin soft and supple a fact much appreciated by the Nursing Profession

Monsol is the product of a Mond Laboratory prepared under strict scientific control

A new invention for sterilising water and making it germicidal

demanding your interest and co-operation

A steriliser that quickly creates germ-free water without affecting the colour, taste or smell

The value of sterile water is obvious to everyone in the Medical Profession An apparatus that will sterilise highly infected water without care or attention, and make that water germicidal so that it resists any chance of further infection certainly fulfils a long felt need To those interested in the restriction of infection spread through micro-organisms present in ordinary water, the discovery of a new and efficient method of sterilisation comes as important news

The inventor is a Munich Physicist, Dr G A Krause

12½ high and ¼ wide Total contents one quart Summary of reports 1 The steriliser is capable of killing off pathogenic bacteria as found in drinking water in very high concentrations 2 The treated water has itself bacteriodal properties

Some £40,000 has already been expended to establish the practicability of the invention, which has been styled Catadyn on account of its dual catalytic and dynamic action The basis of Catadyn is silver in a new highly active state, which quickly sterilises water without affecting its physical properties

The British Catadyn Co, Ltd, has no hesitation in seeking your co-operation in the introduction of this new steriliser which will treat up to 250,000 gallons of water without renewal

A complete steriliser as illustrated above will be sent without charge to Members of the Medical Profession for Clinical (or Domestic) trial, or can be purchased for £2 from the address below A convenient type packed in Monel Metal Container is available at £2 2s

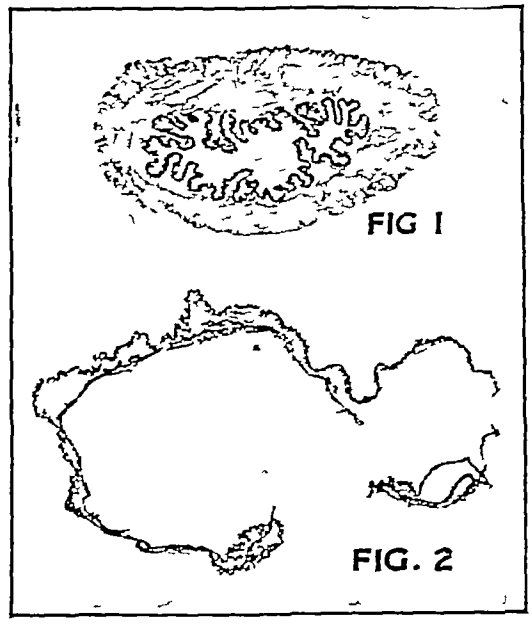
Further Research Work on Gastric Atony

By PATHOLOGIST

We recently published an article on dilated stomach and in it showed photographs of a "Bemax" normal stomach and a "deficiency B vitamin" abnormal stomach We thought it would be of interest, therefore, to go further into the matter and give a description of the histology by means of direct photographs



Rats were used for the test, and both the reproductions shown here are of the cardiac end of the stomach

The mucous membrane in the stomach of a rat is lined with squamous epithelium

Two diets were used in this piece of work, No 1 consisting of 10% of "Bemax" and 90% of a B deficiency food made up of rice starch, casein, mineral salt mixture, and a known tested cod-liver oil Diet No 2 consisted of the same B deficiency diet, and differed from No 1 only in that No 1 contains 10% of "Bemax"

Fig No 1 (magnification x 10) is a photograph of a section of the cardiac end of the stomach of a "Bemax" rat showing the two muscular layers, the areolar tissue and the mucous membrane

Fig No 2 (magnification x 10) is a section of the cardiac end of the stomach of a rat which had been on the same deficiency diet for 4½ weeks It is almost incredible that by placing an animal on a complete B deficiency diet a section similar to that shown in Fig No 2 is produced in such a short time as 4½ weeks

The section in Fig 1—that of a "Bemax" stomach, on further magnification showed the mucous membrane in excellent condition, but the section in Fig 2 on further magnification disclosed marked atrophy of the external muscular layer and extreme atrophy of the inner muscular layer and mucous membrane

Detailed reports of further research work will be sent on request

BEMAX

Max-imum Natural Vitamin B

Samples of Bemax for personal test and full reports of the laboratory experiments outlined above will be sent on application to any Medical Practitioner on request to

THERE IS ONLY ONE

The introduction of Antiphlogistine, more than thirty-five years ago, was the beginning of a movement in therapeutics which has steadily grown, until now it is accepted as one of the established principles of scientific medicine for relief in Inflammation and Congestion

Over ordinary poultices it has the great merit of cleanliness and asepticity

To fomentations it is to be preferred, in that it need be applied only once in twelve hours

By the scientific combination of its ingredients, it puts into practical use the mechanical phenomenon known as "osmotic drainage," which washes out the mucous membranes, or cutaneous surfaces, and which is more efficacious than superficial lavages, which never penetrate the mucosa and merely produce a surface action

The worldwide use of this topical application by the medical profession is evidence of its merit.

Pernicious ANAEMIA

Liver therapy is now an established method of dealing with pernicious anaemia There are, however certain features which do not always respond to such treatment. Notable amongst these is achlorhydria and certain nervous affections It would seem that some factor is missing or deficient in liver which is intimately connected with the gastric aspects of the condition In such cases attention has been turned to the haematopoietic value of stomach tissue with promising results

HEPATEX

Recognised to be the most convenient form of

LIVER EXTRACT

for oral administration Prepared by a standardised process evolved by our chemists Hepatex is so concentrated that a daily dose of four fluid drachms contains the equivalent of 8 ozs fresh liver

Issued in 4 oz. bottles at 12 each

GASTREX

A carefully prepared desiccated and defatted form of fresh hog's

STOMACH TISSUE

Presented as a finely powdered and easily assimilable product and recommended in cases which do not respond to liver extract and especially in the treatment of achlorhydria glossitis and paraesthesia

Issued in boxes of 12 x 10 grammes at 18/- each

PART OF A PASSAGE FROM A MANUSCRIPT WORK OF AËTIUS.—This physician compiled the second Byzantine Encyclopædia of Medicine adding little original beyond marginal notes relating to his own experience. We are however indebted to him for his account of the diseases of the eye ear nose throat and teeth—the best, it is agreed among those of ancient times. He records surgical operations not found in earlier writings such as urethrotomy tonsillotomy and treatment of hæmorrhoids. Some of the lost passages of Oribasius are enshrined in his text. He appears to have made the first mention of cloves camphor and other eastern drugs. The work of Aetius betrays signs of the decadence which medical science underwent in the Dark Ages superstition and mysticism loom large charms and spells being frequently introduced.

Remarks on THE OLD MULTIPARA

THE INFLUENCE OF AGE AND PARITY UPON MATERNAL MORTALITY

BY

A. TEYLAND ROBINSON, M.D. LOND., F.R.C.S.

HONORARY SURGEON HOSPITAL FOR WOMEN LIVERPOOL, HONORARY GYNAECOLOGIST ROYAL SOUTHERN HOSPITAL LIVERPOOL, LECTURER IN OBSTETRICS AND GYNAECOLOGY UNIVERSITY OF LIVERPOOL

THE necessity for the pre-natal supervision of the primigravida is now generally recognized, but the needs of the multipara are not so clear to the public or the profession. When a woman has successfully borne several children she is considered to be an accomplished performer, and the supervision of her pregnancy is looked upon as an unnecessary and expensive luxury. The fallacy of this belief is exposed in the clinical reports of all maternity hospitals, which show the mortality risk for a woman of 40 to be three times as great as that of a primigravida of 18. Among the chief factors for this striking difference are (1) the bodily changes set up by repeated child-bearing, and (2) the physical declension due to advancing age. The significance of these two factors will be considered separately, but it should be noted that in most cases they are contemporaneous in their appearance and similar in their action. The general result of their joint effect upon the maternal mortality is shown in the following tables (slightly modified) published by Menzies [1]:

Age	15	20	25	30	35	40-45
I. *Death rate per 1,000 births (married and unmarried mothers):*						
Pre-natal	0.20	0.17	0.24	0.37	0.73	1.59
Natal	1.81	1.69	1.91	2.41	3.32	7.35
Post natal	1.97	1.01	0.94	1.10	1.42	3.32
Total	3.93	2.87	3.09	3.83	5.47	12.26
II. *Death rate per 1,000 births (married mothers only)*						
Pre-natal	0.13	0.16	0.23	0.37	0.73	1.59
Natal	1.18	1.52	1.85	2.41	3.32	7.35
Post natal	1.28	0.91	0.92	1.09	1.42	3.32
Total	2.59	2.59	3.01	3.87	5.47	12.26
III. *Estimated comparative mortality of primigravidae and multiparae*						
All confinements	2.59	2.59	3.01	3.88	5.47	12.26
First confinements	2.75	3.44	5.01	7.16	10.41	23.73
Subsequent confinements	1.58	1.72	2.51	3.58	5.21	11.86

These tables have been corrected for illegitimacy, and further adjustments have been made for the added risk that is considered to be attached to a first labour, and also for the relative frequency of first as compared with other labours. It is claimed that illegitimacy doubles the risk for the mother, and that a first labour is twice as dangerous as any other, although the author admits that his calculations are not capable of statistical proof, and must be, *to some extent, arbitrary, my own clinical experience* is in agreement with the general principle, but does not support such a high ratio. If, for example, the risk of a first labour were double that of other labours, then the low mortality figure given by Menzies for the 15–20 group, which is composed mainly of primigravidae, would not be credible, especially when the relative frequency of illegitimacy among very young girls is taken into account. Moreover, Menzies himself casts doubt on his own assessment. He quotes Coghlan to show that, the age of the patient remaining the same, the first confinement is always the most dangerous, and that the risk diminishes with the next two or three labours to rise again with each successive pregnancy after the fourth. It will be seen that Coghlan's conclusions support Menzies's principles rather than his figures.

Coghlan's Table

Children borne	Average maternal rate per 1,000 births
1	8.8
2	6.74
3	6.32
4	6.05
5	6.21
6	6.23

The broad conclusions to be drawn from these statistics are strongly supported by clinical experience, and from a consideration of both these sources of information there *emerge three generalizations of great importance. (1)* there is a special risk attached to the first labour whatever the age of the patient, (2) there is a special risk attached to age *whatever the parity of the patient. (3)* increasing parity is associated with a diminishing risk up to the fourth labour, and after that with an enhanced risk that increases *with each successive pregnancy.*

THE EFFECTS OF PARITY

The first act of parturition is associated with two special dangers: (1) a high incidence of toxaemia, and (2) certain mechanical difficulties and traumata.

Although there appears to be definite evidence of the recurrence of toxic symptoms in the subsequent pregnancies of patients who have suffered from eclampsia, eclampsia proper is almost entirely restricted to primigravidae, and the maternal mortality from eclampsia is definitely greater than that resulting from comparable toxic sequelae in multiparae. It is likewise true that the presence of a mechanical obstacle to delivery (competent to produce obstruction) is often unknown in the case of a primigravida until the onset of labour, whereas the multipara has the benefit of her past experience to guide her in the matter.

Both eclampsia and dystocia are largely amenable to pre-natal care, but even when the greatest care has been exercised (and it is doubtful whether 50 per cent. of pregnant women yet receive the necessary minimum of pre-natal supervision) there are fulminant cases of toxaemia which escape detection, and there are women in whom the mechanical relationships of mother and infant remain doubtful until the trial of labour has taken place. Even in normal cases there is the rigidity of the soft parts of the nulliparous pelvic floor to resist dilatation and lengthen labour, whilst the virginity of the birth canal renders bruising, contusion, and laceration of the tissues an almost unavoidable feature of a first labour. These traumata lead to shock, haemorrhage, and sepsis, and, taken in conjunction with the high incidence of toxaemia and dystocia, impose an obvious load on the puerperal risk of the primigravida. The multipara, on the other hand, is protected by her history, for the very fact of past difficulty will draw attention to the present need of special examination and treatment. Too much stress must not be laid on the significance of an uneventful obstetric history, for blind reliance upon a blameless past will create a sense of false security, and may lead to disaster.

It is easy to see why the two or three labours that succeed the first should be less dangerous for the mother: the peculiar difficulties of the primigravida are past: the *soft* parts are no longer a formidable barrier, and the patient is still youthful and vigorous. As parity increases, however, it brings with it certain changes that gradually increase the risk of childbirth—namely, calcium depletion, *loss of muscle tone, and a tendency to haemorrhage.*

Calcium Depletion

Calcium depletion is set up by excessive parity rendering the muscles painful and flabby and enhancing the effects due to loss of muscle tone. In advanced cases this loss of calcium may affect the bones, for although true osteomalacia is rare in this country there are minor grades of this disturbance which escape recognition. It must therefore be remembered that the repetition of parturition and

lactation, especially when combined with poverty, overwork, and underfeeding, may set up a decalcification of the pelvic bones and cause a shrinkage in the bony birth canal that may react upon the mechanism of labour

An interesting clinical commentary on this assertion is afforded by the following analysis of the age-parity grouping of a series of 200 cases of craniotomy taken consecutively from the reports of six well-known maternity hospitals

Craniotomy Table

Parity	Cases	Age	Cases
6 para	17	38	2
7-para	3	39	7
8 para	4	40	7
9 para	10	41	6
11-para	1	43	2
12 para	5	44	6
14 para	2	45	1
15 para	1	46	1
16-para	1	47	1

Of these women, 44 were 6-parae (or *plus*) and 33 were 38 years of age (or upwards) In the majority of cases the early confinements had been easy, and a general survey of the whole group shows clearly that the higher degrees of parity are associated with a special tendency towards a peculiar form of dystocia whose true significance is often missed until the indications for craniotomy have become urgent Few of these patients show any gross mechanical defect, and most of them have a deceptively innocent past history, the difficulty is essentially due to the combination of two factors, both insignificant apart from the other—the first a minor mechanical obstacle to delivery, such as a large child, an incompletely flexed head (persistent occipito-posterior), or a partially decalcified pelvis, and the second a defective musculature, which seriously interferes with the cardiac response of the patient and also reduces and misdirects the expulsive powers of the uterus Unhappily, the case may be regarded as a type of primary inertia and treated along expectant lines, as if secondary were merely an advanced stage of primary inertia

There may be a deficiency of pressor bodies in the blood of both kinds of patients, but the condition is otherwise quite different in its pathogenesis and prognosis, for, whereas primary inertia indicates nothing more than simple muscular weakness, the appearance of secondary inertia indicates the failure of the uterus to overcome a mechanical obstacle to delivery, and is therefore a definite and distinct type of obstructed labour

Loss of Tone

Loss of tone in the uterine muscle is responsible for inertia, prolonged labour, and post-partum haemorrhage, and it also produces a flaccidity of the walls of the uterus that destroys and distorts the shape of this organ This loss of shape permits malpresentations of the foetus, and is a direct cause of dystocia These changes are not restricted to the uterus, but affect the skeletal muscles, the flabby abdominal walls of the multipara resemble the flaccid uterus in their action upon the expulsive powers and their proneness to produce malpresentations (transverse lies and occipito-posterior presentations) Further, the uterus, deprived of the muscular support of the abdominal wall, is itself prone to dislocation, and may assume a position of extreme obliquity (pendulous belly) Severe displacements of this kind, unless they are spontaneously rectified or deliberately corrected by posture, manipulation, or the application of padded binders, may very adversely affect the course of labour Extreme uterine obliquity is a well-known cause of face, brow, and shoulder presentations, which are in themselves a serious menace to the mother, but there is also a deflection of the long axis of the uterus which may seriously interfere with the fixation and descent of the presenting part, and unless the normal relationship of the long axis of the uterus to the planes of the pelvis is restored the efforts of the uterus to push the presenting part into the brim may be entirely misdirected, and thereby rendered quite nugatory This kind of defective uterine action leads to exhaustion of the uterus, and is one of the underlying causes of the special form of obstruction known as secondary inertia

Haemorrhage

That parity produces a tendency to post-partum haemorrhage is a commonplace, but its relation to ante-partum haemorrhage is not so obvious There can, however, be little doubt that concealed ante-partum haemorrhage commonly attacks the old multipara who is pale and flabby and has a trace of albumin in the urine This relationship between ante-partum haemorrhage and age is clearly brought out in the well-known paper by the late Gordon Ley - Analysis of his fifty cases from the point of view of age and parity reveals the following

Age	Cases	Parity	Cases
19	2	Primigravidae	8
21–24	6	1 para	5
25–29	12	2 para	5
30–39	20	3-para	6
40–43	10	4 para	5
		5-para	3
		6-para	1
		7 para	2
		8 para	4
		9 para	7
		12 para	3
		15-para	1

When due allowance has been made for the comparative rarity of childbirth after the age of 40, and also for the relative infrequency of the higher degrees of parity this analysis suggests that concealed haemorrhage (like secondary inertia) is an important feature of obstetric old age

THE INFLUENCE OF YOUTH

The influence of extreme youth is best considered in conjunction with the rôle played by illegitimacy The latter is complex, the majority of patients are in their *first pregnancy, and therefore subject to the risks peculiar* to that state, whilst there is a high incidence of venereal disease and a general disposition towards concealment which, to be successful, involves the neglect of medical aid before, and sometimes during, the confinement As illegitimate cases include a high proportion of all pregnant women below the age of 18, the possible effect of physical *immaturity must also be taken into account*

The exact age at which the pelvic bones and organs reach their maximum development is unknown but it seems unlikely that this should occur at, or immediately after, puberty On one occasion I had an opportunity of observing the growth of the pelvis of a young girl who first came under observation when pregnant at the age of 15½ She was measured during this first pregnancy, and again at the age of 17 and 18 years, and her pelvic measurements were found to have increased *on each* occasion

The presence of a marked degree of under-development must be a source of danger, but it is a rare condition, because *there is a close, protective relationship between* the hard and soft parts of the pelvis on the one hand and the powers of conception on the other In this country, at any rate, there are few expectant mothers with a physical development so incomplete as to be infantile in type, for puberty (and with it the power of conception) does not occur until infancy has passed In Eastern countries, however, puberty comes on at a much earlier age, and pregnancy is relatively common in childhood, and here the presence of dangerous degrees of immaturity has no *doubt some effect on maternal mortality*, although the high morbidity which prevails is probably due to neglect and ignorance rather than to lack of development A clear distinction must therefore be made between the infantile pelvis of the East and the pubescent type which is sometimes found among young pregnant girls in this country It is true that this pelvis shows a certain amount of under-*development, but it is formed of incompletely ossified bones*, and its several elements are united by ligaments of great elasticity, and as a result the pelvic joints are capable of much opening out during labour These several factors produce a general resiliency, which easily compensates for a small reduction in size—in other words, the youthful pelvis is functionally bigger than its actual measurements

Menzies's tables afford an interesting commentary on this aspect of the subject, for the mortality in the 15 20 group is distinctly greater than that of the three succeeding

groups, and clearly shows that extreme youth entails a special danger for the mother At the same time it must be remembered that this group includes all the youngest patients and a very high percentage of illegitimate births and first labours The influence of these several factors cannot be ignored but their individual importance must not be exaggerated, indeed, in comparison with the mortality after 40, the death rate under 20 years of age calls for little comment beyond the obvious conclusion that the very young unmarried mother demands special care and attention before, during and after labour

THE EFFECT OF AGE

The human body may approach old age in a pathological or a physiological condition, although both these states are usually combined, since few individuals are free from some organic defect or weakness Even in the presence of perfect health advancing age causes tissue atrophy or physiological wear and tear that reduces the activity of the organs of the body and absorbs their reserve power Any such progressive impairment of function will reach a point in the course of time at which the whole of the reserve power is fully mobilized and the individual is incapable of further effort The result of these changes is well shown in the athlete whose physical perfection declines between the age of 25 and 30 and is lost five or ten years later In the same way as loss of youth unfits the athlete for great effort so does the effect of time react upon the pregnant woman and make her less fit to meet those exceptional demands of parturition which fall chiefly upon the excretory system during pregnancy and the musculature and heart during labour

The local effects vary in kind and degree with the particular organ affected, but in most women of advancing age there are definite changes in the myocardium, kidney, and uterus The general result of the whole process is to lower the resistance of the patient, to reduce her capacity for work, and to render her more sensitive to fatigue and shock

Pathological Age

The action of advancing age upon any organic defect or disease is dependent upon many factors, and especially upon the site and nature of the lesion Many diseases are progressive in character, and their disabling effects increase automatically with age In most women, therefore, the ravages of time are not only physiological, but pathological in type, and, as might be expected, the increase in puerperal mortality which sets in after the age of 35 runs to a large extent parallel with the rising mortality rate found among comparable non-pregnant women

The present communication is not concerned with the role of independent organic disease except in so far as it has a bearing upon the relationship of age and parity to parturition, but it appears to be sometimes forgotten that an organic defect or disease is no respecter of persons but affects the pregnant as well as the non pregnant woman, and therefore constitutes an important contributory cause of death during childbirth among women belonging to the older age groups Furthermore, the process of reproduction has a potent influence upon many disease, either by enhancing their effects or stimulating the development of their lesions Excessive child-bearing may therefore shorten the time required by an organic disease to arrive at its lethal stage thus both age and parity may form a close liaison with organic disease, and through this medium *exert an important if subsidiary influence upon* maternal mortality

TREATMENT

It has been shown that age and parity have an influence upon child bearing that is potent, reciprocal, and often symbiotic but it is not possible to lay down any hard-and-fast rules concerning treatment Each case must be judged on its own merits, and a careful general and local examination made due consideration must be given to the age of the patient and the amount of physiological wear and tear (physiological factor) and also to the presence of pathological lesions and the stigmata of excessive parity (pathological factor) These factors combine to form what may be termed the obstetric age of the patient which it must be remembered may differ greatly either from her actual age or the number of her pregnancies When, however obstetric old age is discovered as a result of this investigation, it is necessary to determine the character of the pregnancy before proceeding to treatment for this purpose some ante-natal classification is essential, and the following method of dividing all pregnant women into three groups is both simple and useful

Group 1 The grossly abnormal group (eclampsia tumour severe pelvic contraction, heart disease etc.)

Group 2 The apparently normal

Group 3 The doubtful.

Group 1—The treatment of the first group follows well recognized general principles that are largely independent of both age and parity

Group 2—In this group the age parity factor is of decisive importance for when a woman has once entered obstetric old age she can never be regarded as perfectly normal and hence all old multiparae who do not belong to Group 1 must be deliberately placed in Group 3

Group 3—No generalizations are permissible with regard to this group, which is often a source of anxiety and difficulty to the most experienced ante-natal physician Into this class must be put women with a minimal pelvic contraction, a slight trace of albumin and those who reveal some minor organic defect it includes others who reveal no obvious abnormality, but give an unsatisfactory history of forceps deliveries or stillbirths, and, last but not least the special type with which this paper is primarily concerned—namely, the old multipara

The treatment of this type of patient depends upon the application of the following rule that whereas one minor disability when acting alone is often harmless, the combination of two or more minor defects mechanical or otherwise, *is always potentially dangerous It produces* a symptom-complex of a gravity far beyond that of its component parts and one that demands much more drastic treatment than would at first sight appear to be justifiable

It is essential that every effort should be made to avoid a second complication in a pregnancy that is already even slightly abnormal and if this cannot be done the case must no longer be classified as doubtful, but regarded and treated as belonging to the grossly abnormal group No *class of patient affords a better example of this than the* old multipara, and the high mortality seen among these women will persist until it is generally recognized that *the symbiosis of old age and parity with other minor* defects is both powerful and dangerous, when, however the importance of this principle is conceded the treatment of the old multipara and her companions in the doubtful ante-natal group is much simplified

It should be generally known that the mortality risk increases with the age of the mother and therefore child-bearing should be undertaken in the earliest years of married life, and not postponed to some more convenient time in the future *Families should not be restricted to* one or two children, because such restrictions by relatively increasing the number of first pregnancies raise the general maternal mortality and are therefore prejudicial *to the interests of the State Four or perhaps five* children should be regarded as an ideal number but further reproduction should be discouraged on account of the increased risk that attaches to the higher degrees of parity Some of the deleterious effects of age and parity can be counteracted in a general way by improving the sociological conditions of the community with regard to food, wages and housing The provision of an efficient obstetric service that includes ante-natal supervision is capable of reducing the maternal mortality of this country a large proportion of which disappears so quickly in the presence of economic distress and indifferent midwifery

The universal application of ante-natal care is urgently *required* but it *can never replace* the need for skilful attendance during labour it can much more even be should be devoted to the post-natal period and the process of involution and lactation Unavoidable obstetric injuries should be adequately repaired and every effort made to

prevent subinvolution and the development of displacements, which not only impair the pelvic musculature, but lead to defective uterine action in subsequent labours

Under such a regime, the pathological phenomena of old age will become rare, but the old multipara will continue to bear children and to require the special attention of the midwife Much can be done by simple conservative methods to mitigate the evil effects which have already been described, the exhibition of iron and calcium combined with a suitable aperient has a most favourable effect on the muscle tone, and it may usefully be combined with 0 5 c cm of pituitrin twice a day during the last week or so of pregnancy, this not only improves the tone of the uterus, but in many cases brings on labour, to the benefit of the patient Uterine distortion and dislocation must be controlled, and the resulting malpresentations and malpositions corrected by manipulation or the application of padded binders *The induction of premature labour* before or at term is a useful prophylactic measure for women who habitually produce big children, in this connexion it is well to remember that, from the functional point of view, the pelvis gets smaller as the patient grows older

During labour the application of forceps or version in certain cases will relieve the efforts of the uterus and reduce the work of the myocardium, and the third stage must always be conducted with the greatest possible care A good deal can be done by these conservative measures to reduce the maternal risk, but the obstetrician should not hesitate to employ more heroic treatment if he believes surgical intervention to be necessary It may require a certain amount of moral courage to suggest operative delivery to a woman who has already been delivered many times *per vias naturales*, but a careful review of the situation will show the wisdom of such advice for carefully chosen cases, indeed, it is safe to predict that in a more advanced epoch the majority of 8-paras and all women of 40 will be delivered by Caesarean section

The Morison Lectures

ON

NERVOUS SEMEIOLOGY, WITH SPECIAL REFERENCE TO EPILEPSY.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH ON JUNE 2ND, 3RD, AND 4TH, 1930,

BY

S A KINNIER WILSON, M D , F R C P ,

NEUROLOGIST AND LECTURER IN NEUROLOGY, KING S COLLEGE HOSPITAL, SENIOR PHYSICIAN TO OUT PATIENTS, NATIONAL HOSPITAL, QUEEN SQUARE

LECTURE II —SYMPTOMS INDICATING INCREASE OF NEURAL FUNCTION

PASSING attention has already been directed to the general division of nervous symptoms, whatever their order, into those expressive of increase and decrease, respectively, of nervous function The classification is applicable as well to those of the neuro-sympathetic system as of the psychical series Possibly the term "increase" is not the most satisfactory that might be selected, it is taken to include symptoms and syndromes indicative of escape or release of function, in addition to such as presumably come into existence through stimulation or excitation

Clinical experience affirms that an extremely large part of neural semeiology is included in this first main division, but the two sets are not mutually exclusive by any means, convulsions and paralysis can occur in the same subject, not, of course, simultaneously in the same part, yet in immediate sequence, while a limb already paralysed may become convulsed the phenomenon of anaesthesia dolorosa is constituted by the synchronous combination of subjective pains or neuralgia referred to a region which is objectively anaesthetic, involuntary flexor spasms can take place in paraplegic extremities that the patient cannot voluntarily innervate Further, not a few of the semeiological concomitants of epileptic fits are substantially indicative of functional inhibition, and some varieties of seizure are considerably more inhibitory or akinetic than kinetic or excitatory Thus the question may arise whether in point of fact any symptom group is not accompanied by evidence of both one and the other physiological actions, but this is probably true only of the higher levels of the nervous system, and in the special sense that if an excitatory process is to exteriorize itself it must succeed in overcoming inhibition No escape-phenomena can accompany paralysis at the level of the lowest motor neurones, but the same affection of the highest almost inevitably entails the likelihood of release below Whether inhibition is constantly present is doubtless matter for discussion, if I become conscious of the aching of a carious tooth it is always allowable to assert that inhibitory control must be in abeyance ere impulses from dental end-organs reach the cortex to give rise to (I do not say "to be changed into") sensations, yet of the actual existence of such a mechanism, still more of its intimate nature, we are likely to remain in considerable ignorance As regards the general sensory system data suggesting the possibility of sensory inhibition have been marshalled recently by Foerster (loc cit), while in respect of the visual system some experimental work by Brouwer[1] has seemed to prove the existence of an *efferent* system accompanying the optic tract from external geniculate to occipital cortex, conceivably inhibitory in function Thus some basis is provided for the hypothesis, at any rate, we know that different functional levels of the nervous system enjoy comparatively independent life, and that those of higher are, as it were, protected against those of lower grade When we speak of centres "representing" lower units in more complex ways and of their constituting also reservoirs of energy, we should not overlook the possibility of their having inhibitory functions too Hughlings Jackson has somewhere spoken of these upper centres as forming "resisting positions", owing thereto, activities of the highest levels can proceed without interference from the environment (the life of thought would be intolerable otherwise) on the one hand, and *without effecting reactions* on it on the other It is matter of common knowledge that impulses from the periphery must in numerous instances never penetrate to the cortical level, being damped down or turned off and shunted to the efferent side through infracortical reflex arcs Muscular tone maintains the subject's erect position by impulses derived from the sensory periphery and passing over a mesencephalo-spinal circuit of which he is completely unaware Similar comment applies to the abundant activities of the neuro-sympathetic system, on rare occasions only are we consciously aware of them Protection may be justifiably assumed in respect of cortical action, and in consequence thereof it is permissible to argue that symptoms whose character partakes of increase or release of neural function must break down resistance and neutralize inhibition ere they come into being But with this proviso much in neurological semeiology consists essentially of "positive" symptoms, *signifying enhanced* or exalted activity on the part of the mechanisms involved

We may now consider one or two specially selected aspects of the most obvious type of "positive" syndrome—namely, that described in semipopular phraseology as "attacks," "seizures," or "fits"

On various previous occasions I have dealt with one or other side of this subject, though not before in the fashion now to be adopted Most neurologists are familiar with the Jacksonian conception of three physiological levels or grades in the central nervous system, spoken of by him as the highest, the middle, and the lowest respectively Of these the first he took to have its anatomical substratum in the frontal lobes, the second or middle level corresponded to that part of the cortex where are situated the Rolandic centres, the lowest was ponto-bulbar in position We need not follow Jacksonian conceptions slavishly in the present connexion, *seeing that he himself was ever willing to discard* unsubstantiated hypotheses, at the same time, and in spite of its schematic character, I shall for my present purpose utilize his theory in modified form, the highest

level I shall assume to correspond to the whole cortex outside and above anatomical projection-centres, the latter constitute the middle level, while the lowest is taken to include what may properly be regarded as the old nervous system—namely, basal ganglia brain-stem and cerebellum, and spinal cord. With this tripartite division of the neuraxis we may examine the relation of fits, however diverse and heterogeneous, to increase or escape of function in respect of each of these regions in turn.

It is, of course, necessary at this juncture at once to underline the fact that radiation of release or excitatory phenomena characterizes numerous attacks or seizures, whose manifestations are not in their totality confined to one level only. Hence *differentiation to facilitate description* can scarcely avoid becoming schematic also, though not in any sense arbitrary.

FITS AT DIFFERENT PHYSIOLOGICAL LEVELS

In accordance with what has just been suggested a theoretical division into highest, middle, and lowest level fits respectively is conceivable but can these be distinguished clinically, and, if so is the fact of any clinical value? I am of the opinion that both questions may be answered affirmatively.

HIGHEST LEVEL FITS

These must depend for their intrinsic characters on the functions of the highest level, naturally. Discarding all such question-begging terms as psychokepsy, psychical equivalents of epilepsy and analogous expressions we may assert that any kind of attack signalized by phenomena of a psychical type is *pro tanto* a highest level fit. From this standpoint every fit preceded by a definite aura must be placed in the class so far at least as that symptom is concerned for the aura is nothing more or less than a sensation or hallucination, and therefore belongs intrinsically to the psychical series. It must be regarded as the earliest component of the fit, its prelude, but not (as was formerly supposed) its cause. By no means invariably present, it practically always reproduces itself in the same form for each of the attacks of the person concerned. The aura ranges over the whole field of sensation inclusive of the special senses, and indeed of feeling memory, and other psychical elements. It may be simple and crude or complex and elaborate, or these two opposite features may occur in the same case with reference to different sensory modalities. Sometimes clear and impressive at others it is elusive, vague fleeting and difficult both to recall and to express. The question arises whether distinctions can be drawn, for any given sensory system between auras of lower and of higher grade and whether those of the former category are initiated in projection- as opposed to association-centres—that is start in regions belonging, *ex hypothesi* to the second or middle group. For that matter, fits of lowest level type if an aura is present at all, must somehow be able at the outset to influence the cortex—assuming that to be the seat of consciousness. Evidently the way must be open for impressions to ascend to the percipient region in the latter case part at least of the fit, therefore, must be of *ascending* type (a significant consideration) and when the aura seemingly starts at the middle level there must be neuronic integrity again in an ascending (transcortical) direction for its underlying impulse to reach the perceiving cortex (whatever and wherever exactly that may be taken to be). For instance, I recall the case of a child whose visual aura consisted of what she described as "twinkles" in the right visual field—crude flashing medleys more or less like coloured stars—and I contrast it with that of another patient who, as he sat in a summer-house in his garden, saw a white-robed figure pass over his garden wall on the left with back towards him, and move slowly towards the french window of the room which opened on to the lawn as the figure reached the window he lost his senses. Clinically again, an auditory aura constituted by a loud bang seems far removed from that of the patient who declared, 'I seem to hear everything that has ever been said to me in all my life,' or a sudden stench in the nostrils from 'a series of odours, as if I were passing a perfume-shop'—to quote the words of another. Are we to consider the simple crudities of the one class to represent excitation in projection-centres, the complexities of the other to stand for associational or highest level excitation? Possibly we should, but it is questionable whether such distinctions can be drawn with precision, nor from the viewpoint of cerebral physiology is it clear that projection- and association-centres for a given sense modality, are separable with any exactitude, although for anatomical reasons it may seem justifiable to consider them apart. A coarse and powerful sensation of "pins and needles" in the fingers perhaps points to excitation of projection-centre or -system, and it appears to belong to an entirely different category from the aura of the 'dreamy state'—that condition in which the patient at the oncoming of his fit experiences a series of panoramic pictures, or lives again some incident or incidents in his past life or feels as though he were in some other place than the actual one or is conscious of a *deja vu* feeling and so forth. These peculiarly interesting auras I have recently analysed and illustrated and shall not here say more of them. Often enough the elaborateness of the experience will not permit of its being explained by reference to one sense avenue only, thus a patient's aura consisted in his taking the end position of a row of twelve *men in military formation*, a superior in rank stepped forward and boxed the ears of each in turn, knocking him down while our man stood in fearfulness awaiting the inevitable termination, as his ears were boxed he lost his senses.

From the features of the aura it is proper for the clinician to endeavour to determine its approximate localization, since this may be of immediate practical value. At the same time we are not always in a position to say whether it arises in a lower centre, or in a higher centre representing the other. This applies in particular to auras *presumably of a neuro-sympathetic kind when for instance* in what for other reasons we take to be a lowest level fit the initial symptom is "pain round the heart like knives" (as in a recently observed case) does the excitation arise in the ganglionic collections of the organ itself or in viscero-sensory centres of paravertebral chain or spinal cord or in the dorsal nucleus of the vagus or at some conjectural higher spot still, re-representing the heart. The "dreamy state" whether it occurs in connexion with olfactory and gustatory hallucinations or not, suggests a disorder of function whose starting point is the *temporal cortex of one or other side spreading* probably by definite transcortical paths to the occipital lobe or occipito-parietal cortex for the visual component. We can conceive of the aura as ranging from excitation of a small portion of a sensory centre to implication of wide areas of the associational cortex the psychical stuff it is made of is one and the same, whether we are dealing with tingling in the great toe or a feeling of being back in a former existence.

Thus regarded I seek no differentiation between the auras of hysterical fits and of organic epileptic seizures. I cannot detect any physiological difference between one and the other. At the sound of Zeppelin bomb-dropping in London during the war a soldier patient hopped out of bed and pushed his pillow before him as he crawled on his stomach along the polished floor of the ward re-living graphically his experience of the trenches when seeking cover, at the end of the room the hysterical fit came. Elaborate the aura was but not different in kind from that of some temporal fits. However unfamiliar the conception may perhaps be to some it is surely proper to consider hysterical seizures as highest level fits *par excellence*—that is, fits of which the phenomena are largely confined to that level. To my mind such divergencies as exist between hysterical and epileptic seizures are explicable with facility in terms of the functions of the physiological level at which the phenomena are occurring. This is true in particular of the motor display. Every clinician who has witnessed hysterical attacks is impressed by the quasi purposive character of the movement they have a meaning they appear to be directed *towards* an end the cruciform posture *arc le cercle attitudes passionnelles*, and so forth of the hysteric reveal what in the subconscious mind. But are movements of analogous

nature foreign to the ordinary major epileptic fit? By no means. It is most important and significant to note that normal, co-ordinated movements frequently occur apart from those that are termed "convulsive", during one or other part of the fit the epileptic patient may make champing movements of his jaws, smack his lips, spit, or clutch at his throat, after the convulsive period, and while still unconscious, he may exhibit other motor phenomena such as plucking at his clothes, undressing, running, and what not. A young man once under my care, suffering from a left frontal abscess, invariably waved his right arm round and round in circles ere overwhelmed by unconsciousness. The movement was co-ordinated, and as such clearly referable to the highest motor level—that is, to a cortical region distinct from the Rolandic. It is possible that the head and eyes deviation which is a common first sign of the generalized epileptic fit is caused by implication of the corresponding centre which the experimentalist has shown is situated in the frontal lobe, separate anatomically from middle level centres in the Rolandic cortex.

Moreover, the whole motor content of some attacks of the epileptic class is not convulsive at all, but strictly co-ordinated. A patient of mine suffers from fits in which he turns very pale and loses touch with his surroundings, but never falls, he raises his closed fist and shakes it, blinks with his eyes, then looks sideways as though to see round a corner. The fit is over in about a minute. His maternal uncle suffered from major epilepsy, also a cousin. The motor phenomena of petit mal are often co-ordinated rather than convulsive, as any close observer can convince himself. In this connexion it is of interest to recall Jackson's contention that the anatomical substratum of petit mal attacks is situated in the frontal lobes.

We see, then, that among the symptoms referable to excitation or transcortical release on the highest physiological level are (1) an aura in consciousness, and (2) types of movement co-ordinated and quasi-purposive, occurring either in association with convulsive movements or by themselves. To these I now add (3) post-convulsion movements and actions of the same high level class. Known for years under the term "post-epileptic automatism," the manifestations of this phase clearly belong to the group of escape-phenomena, purposive in appearance, none the less in the strict sense they are completely involuntary, and, being such, the patient is not responsible for them in a medical or forensic sense. Their duration ranges from a disorder of a few minutes to prolonged fugues, indistinguishable from those of hysteria. Recently a patient, living at Catford in South-East London, went for an afternoon stroll to a neighbouring pond, he was next seen taking a motor bus to Croydon, from there apparently he walked right across London to Paddington station, took a ticket to Penzance in Cornwall, and "came to himself" about 4 o'clock in the morning in a Cornish express far in the West. His mind was a complete blank after he had entered the motor bus. A sufferer from inveterate petit mal, there can be no reasonable doubt that his fugue succeeded a brief attack unrecognized by any passer-by. The medico-legal import of such states is at once apparent, for the subject is to all outward appearance normal. During the war an epileptic patient boarded the London train at Brighton, it stopped on the Grosvenor bridge over the Thames, just outside Victoria station, here he opened the carriage door and walked over the metals, where he was challenged by a sentry guarding the bridge. Unable to furnish a clear account of himself, he was arrested and given six months' imprisonment. Only on appeal was the evidence of those who knew his case accepted—namely, that he must have had a fit in the train and been in a state of post-epileptic automatism when he came in contact with war regulations. An even more impressive case, because of its criminal aspect, was that of a man in early middle life who sustained a severe accident in the frontal region and thereafter on at least three occasions developed fugues of greater or less duration (in one of which he came from Wales to London consciously unaware of the fact) preceded by "attacks" in which he turned pale, his eyes became fixed and staring, and for the time he was oblivious of his surroundings and did not hear or could not answer questions addressed to him. In one of these turns he, unfortunately for himself and for the child, threw, or let drop, his infant girl, 6 months old, out of a bedroom window on to a stone-flagged yard, where it fractured its skull and was killed. After his arrest on the capital charge, I gave evidence on his behalf to the effect that he had been in a state of fugue and was irresponsible for his actions, since unconscious of them, medically speaking, and I had the satisfaction of contributing to the favourable finish of the case.

Conditions of this kind seem far removed from the crudities of an ordinary generalized epileptic seizure, but I urge the irrationality of delimiting epilepsy by its middle level semeiology and insist that for clinical and scientific purposes both ante- and post-epileptic phenomena form an integral part of the whole. These, as must clearly emerge from any adequate consideration of the matter, include symptoms on the highest physiological level of activity, frequently if not invariably. In themselves they present close resemblances to symptoms which we call "hysterical," and if this view commends itself then it seems otiose to try and formulate distinctions, for they can scarcely amount to differences. The name we give to a symptom or syndrome is of purely secondary significance, its characters and pathogenesis must guide us in coming to any conclusions as to its nature.

Finally, in this connexion, I should like to direct attention to an aspect of epileptic consciousness which provides food for thought. Now and then one comes across a case where the subject declares that his attacks have been actually pleasant, or at least have been associated with, or left in his mind the impression of exhibiting, some element of a distinctly pleasurable kind. An intelligent lady of 32 suffers from attacks which belong to the uncinate variety of so-called idiopathic epilepsy, and are characterized by a "dreamy state" aura with a strong feeling of familiarity or *déja vu*, in her own words, "I feel as if my mind and my body are coming apart", or again, "I can see myself walking in the garden as if my mind were looking at myself from afar". This peculiar mental state is accompanied by a definite feeling of pleasure, so much so that at first the patient used to welcome the sensation as a "dream of delight", the precise pleasurable element, however, she has never been able to specify. At a later stage the fits became few and far between, and confined largely to the briefest of *déja vu* auras without any pleasurable component, for nine years now she has had none at all. A more recent case is that of a young woman who has been epileptic for some ten years, up to the age of 18 the attacks seem to have been little more than a kind of prolonged petit mal, and were accompanied by a highly pleasurable feeling, "I felt that I had been away somewhere in a pleasant dream, which I was enjoying to the full". Looking back on it, she was convinced it had been delightful while it lasted, and that this was due not so much to a physical as to a mental state. Later, the fits became more severe and typically those of grand mal, and since their development (with severe post-epileptic headache and myalgia) the pleasurable element has vanished and its place been taken by a vague and ill-defined dread or apprehensiveness, experienced now as a prodrome to the attack. I may also cite the words of another patient, whose case is given in some detail elsewhere[19]: "I used to feel I had had a previous existence, and that in these sensations I stepped out of myself into the other existence. I felt as if my brain were leaving my body for the moment. I used rather to welcome it, as a not unpleasant feeling".

The explanation of the rare appearance of this pleasurable emotion in connexion with epileptic auras and states is far from easy. The common epigastric aura not infrequently brings in its train a feeling or emotion of fear or terror, as of something impending, something dreadful about to happen, although seldom does it embody any specific ideational element with which the fear is linked. From over 3,000 cases of epilepsy some 92 were collected by Gowers[20] into a group distinguished by "psychical auras" (since all auras are psychical the term is imprecise), and

of these about one third were characterized by a feeling of alarm or fright, but no allusion is made to the opposite variant Perhaps it is not a coincidence that in each of the three personal cases just quoted the pleasurable emotion occurred in connexion with "dreamy states," though I do not know how to account for it except on the speculation that by some temporo-thalamic path a thalamic element entered into the composition of the whole Nor do I understand why, if such be the case, the condition should not occur with greater frequency

Middle Level Fits

In accordance with long-established usage the term "epileptiform" convulsions should be confined rigorously to cases of Jacksonian epilepsy—that is, fits of the middle physiological level I shall limit attention at this time to one or two problems presented by what may be termed "reflex Jacksonian epilepsy"

Reflex epilepsy is an expression which has never been defined with any precision It has been employed in a general way to connote the development of fits as a sequel to peripheral irritation of one or other kind, and older treatises enumerate as examples those which have been thought consecutive to adenoids, errors of refraction, carious teeth, dyspepsia, helminthiasis, tight prepuce, and what not The phrase "secondary epilepsy" was proposed long ago by Nothnagel for rare cases in which actual injuries of peripheral nerves were followed after an interval by epileptic seizures, with or without an aura referable to the part affected It seems curious that with the wealth of peripheral nerve lesions produced by the war no such cases appear to have been recorded, so far as I am aware We may recall also in this connexion the experiments of Brown-Sequard,[21] who after various operative procedures (hemisection of cord, section of sciatic) on animals (especially guinea-pigs) found it possible to develop in them convulsive attacks by excitation of an "*epileptogenous zone*" *over face and neck* (*corresponding* in distribution to part of the fifth and to upper cervical nerves) His results were confirmed by some observers and criticized by others, in 10 of 41 guinea-pigs with cut sciatic Bramwell and Graham Brown[22] produced "fully developed" fits by stimulating the zone after some seven weeks had elapsed We may note, however, that from descriptions recorded generalized and not unilateral convulsive movements were commonly obtained It is a precarious proceeding to apply to the case of man conclusions derived from experiments on much lower animals, but from time to time instances have been published of reflex epilepsy of this kind As long ago as 1886 Hughlings Jackson[23] showed at the Medical Society of London a boy of 7 who exhibited epileptic fits whenever his head or face was touched, express mention is made of the fact that when he was aware he was going to be touched none occurred *In the discussion following this paper somewhat* analogous cases were alluded to by various physicians, of which one is of considerable interest, that of an epileptic with disease of the femur 'When dressings were applied, or when the sinus was probed, the man had severe epileptiform seizures Amputation was performed, and the man had only one epileptic attack afterwards, and that was at the first dressing, when the 'epileptogenous' area was touched" More than ten years previously, in 1874 to be exact, Dr James Dunsmure,[24] physician to the Royal Hospital for Sick Children, read before the Medico-Chirurgical Society of Edinburgh a paper on the case of a boy of 5, who suffered from attacks of what was described as "temporary loss of voluntary power" whenever anything touched his head without his foreknowledge The details of the fits suggest that they were mainly akinetic or inhibitory, although on one occasion the muscles of the right arm and leg were "slightly convulsed" Later information about the case was sent to Jackson by Dunsmure and will be found in one of the former's Neurological Fragments[5] (No 13, 1895) From it we gather that the youth eventually died of peritonitis, and that his brain was examined by the late Dr Alexander Bruce who in 1892 was pathologist to the Royal Infirmary No changes were found in pons or medulla (Jackson had believed the fits to be of lowest level type), but many of the cells of the grey matter of the cortex were vacuolated

In a paper on "Epileptic variants"[6] I have mentioned the case of a little girl whose first fit occurred when the hat-elastic under her chin slipped up and hit her nose and allude also to other kinds of reflex attack which have come under notice, inclusive of so-called acoustico-motor epilepsy

Recent practice has brought under my care two cases of what seems to be genuine *Jacksonian epilepsy of reflex origin* The first is that of a woman of 51, whose attacks began eight months before her admission to hospital towards the close of 1929 I shall quote from the records of the case made by my house-physician, Dr Denny Brown

> She began to have attacks of unconsciousness whenever anything touched her *right ear or her head just behind the ear* (for instance putting her spectacles on) These began with a twitching and tingling pain in the right side of the face and a clicking noise in the head. She remained conscious but could not say what she wanted to Weakness and numbness of the right side of the body *lasted* from one to twelve hours after each attack Six weeks ago she began to have similar attacks brought on by some stimulus to the right foot or the right leg below the knee (for example pulling a stocking over the foot) These also began with clicking in the head and a tingling pain and twitching *starting in the right foot and passing up the right leg and down* the right arm while also involving the face on that side They were followed by unconsciousness for a few minutes and by residual aphasia numbness and increased weakness of the right limbs for an hour or two
>
> Two attacks have been observed, the first produced when eliciting the knee-jerk on the right the second by pulling the bedclothes away from the right leg Both began by tonic extension followed by twitching of the right ankle knee and hip and then of the right arm and face immediately after this the whole left side at once became involved The duration of unconsciousness was about four minutes followed by aphasia and then marked perseveration with weakness of the right arm and leg and extensor plantar response on the side flexor on the left Complete recovery ensued three hours after the onset with return of all signs to those found on admission.

An exploratory operation over the left Rolandic cortex showed nothing else than a milky appearance of the arachnoid in the vicinity of the superior cerebral veins with no evidence of neoplasm There seems little doubt that the pathological basis of the condition is one or cerebral arterio-sclerosis, a very common antecedent to Jacksonian epilepsy, but the peculiar features of the case may best be examined after a note on the second

> It is that of a young man who at the age of 30 some seven years ago began to suffer from Jacksonian attacks beginning in the right thumb or in the fingers of the right hand These were usually brought on by a start on occasion spread typically over the right side and ended in unconsciousness and generalization with tongue-biting Examination yielded a negative Wassermann reaction in the blood and since nystagmus moderate in degree was occasionally present on lateral deviation in either direction while the optic discs were distinctly hyperaemic with slight blurring along the inner edges a tentative diagnosis of intracranial tumour was made or, alternatively of disseminated sclerosis.
>
> The case has been followed with the greatest closeness since 1923, during that time no material change has occurred very occasionally a right extensor plantar response has been obtained the tendon reflexes on that side are brisker than the left and the discs remain as before without atrophy

To illustrate the phenomena in this unusual case a series of incidents which have started the fits may now be described, as narrated by the patient himself

1 When he was walking along in rain with his umbrella up his right hand which was some little way up the shaft was struck by the catch slipping and the frame coming down on it

2. While he was carrying a rather heavy parcel in the arm hand the string broke and gave the limb a slight jerk aggravated by his making a quick attempt to catch the parcel with that hand as it was falling

3 As he was pressing rather heavily with a file in his right hand on an object he was working at the file suddenly broke

4 When he was holding two small articles in his hand and endeavouring to screw them together one slipped out of his grasp with some little force.

5 On two occasions lying in bed half asleep, with his right arm underneath him, "pins and needles," presumably from pressure, have commenced in the periphery of the limb

In all of these (and other) instances a direct "start" or "jolt" of the right upper limb, distally or throughout, has been the immediate precursor of the Jacksonian attack

6 He once tripped his right foot over an accumulator which he did not notice, and fell

7 On a station platform, stepping forward to take a tram, his right foot caught in an unevenness of the ground and he stumbled

In these instances it was the right leg or foot which received the shock

8 On several occasions someone has brushed past him or knocked into him unexpectedly, although not specially on the right side

9 A sudden and loud noise will initiate the sensation in the right hand it has also developed when a door was unexpectedly opened in his face as he approached it without touching him Walking with a friend the latter stumbled over a rut in the road and gave the patient a "fright" Again, in similar circumstances the friend scraped a piece of paper along the ground noisily with his stick, and this proved an excitant Sitting one day on a seat in his garden he was gazing at his cat, which suddenly jumped on to a high seat opposite, missed its footing, and fell giving him a "start"

From these latter illustrations we observe that stimuli reaching the sensorium by the avenue of sight or hearing must be added to the possible excitants of the Jacksonian attacks, and that these are not restricted to direct stimulation of either the limb or the side by which the fits invariably commence

As already remarked, some only of the seizures go so far as to become generalized and cause unconsciousness, others are of an intermediate class One which was observed was of the following nature

Whenever the aura spread up the right arm from the ball of the thumb (on this occasion) the right arm exhibited characteristic clonic twitching, breathing became laboured, and the face congested almost to cyanosis, while the legs gave way and the patient sank to the ground Twitching ceased at the shoulder though facial grimacing on the right side was in evidence, and thereafter the right arm and indeed the musculature generally was completely relaxed He began to talk "nonsense," while his eyes wandered irregularly from side to side A quarter of an hour later recovery ensued At no point in this attack was loss of consciousness absolute

The exact mechanism by which reflex Jacksonian epilepsy comes into being is by no means clear That in these two instances we are dealing with hyperexcitability of cortical reflex arcs seems obvious, and the presumption is that sensorimotor centres in the Rolandic cortex are in a state of irritability, with the corollary that transcortical inhibition is at the same time defective To my way of thinking the existence of cortical reflexes is of much significance for the understanding of many of the symptoms of neurology—reflexes on a high physiological level over which, in abnormal circumstances (such as the presence of actual local cortical lesions), what we call in our ignorance "volition" can exercise no inhibitory effect I am tempted in this connexion to quote the words of a famous teacher of the old Edinburgh school, of whom I have heard Sir Byrom Bramwell, as well as the late Sir David Ferrier, speak with deep appreciation I refer to Professor Laycock,[27] and cite from an article of his dated eighty-five years ago

Four years have elapsed since I published my opinion, supported by such facts as I could then state, that the brain, although the organ of consciousness, is subject to the laws of reflex action and that in this respect it does not differ from the other ganglia of the nervous system I was led to this conclusion by the general principle that the ganglia within the cranium, being a continuation of the spinal cord, must necessarily be regulated as to their reaction on external agencies by laws identical with those governing the spinal ganglia and their analogues in the lower animals

Observations and arguments like those satisfactorily adduced in proof of the existence of the reflex function of the spinal ganglia may be brought forward in proof that the cerebral ganglia have similar endowments

The motor area of the mono physiologist is nothing more or less than a motor or sensorimotor ganglion pushed up into the neopallium and it would of a truth be disconcerting to our ideas of neural continuity were that ganglion to prove of a completely different physiological order from those situated at a lower level Nature cannot surely make any abrupt "jump" from one class to another, for example, it would be a curious thing if what we call "mental states" were *suddenly* to make their appearance, and only at a final stage Lloyd Morgan, Parsons, McDougall, and others like the view (adumbrated long before by G H Lewes) that consciousness exists on different physiological planes, in its simplest form, according to Parsons,[28] it is a mere sentiency—the emergence of an "awareness of a change in the environment" This awareness is consciousness on the reflex plane, it is tinged with affective tone and with a minimum of cognition McDougall[29] says "It seems probable that the actions of even the lowest animals imply a vague awareness of something together with some vague forward reference, some vague anticipation of a change in this something" Carrying the idea further, and to its logical conclusion, we may affirm that at the cortical level in man reflex action may be, must be, accompanied by full awareness, by consciousness on the plane either of instinct or of intelligence, yet in itself that reflex activity may none the less exhibit all the qualities of the same when expressed through lower mechanisms

The clinical phenomena of the two cases which we have been considering demonstrate the occurrence of pure reflex response to extrinsic stimuli through arcs whose nodal point is certainly situated in the cortical grey matter, in the second example the readiness of these cells to discharge is proved by their doing so as a sequel to afferent impulses reaching them not merely along the paths belonging to the arc in a topographical sense, but also by routes from sense-organs of another series What seems to be an essential in the case is that the arc should be seized unawares, the patient remarked, apropos the incident of the paper scraped along the ground, "Had I seen it happen the fit would never have occurred" The comment suggests his capacity for inhibiting the reflex is still in being provided he is warned and therefore prepared, but in the case of the other patient the element of surprise does not appear to be a necessary factor, for she informed me when I first saw her that fits had taken place though she knew that her leg or foot was about to be handled Absence of awareness, however, also was essential in the case of the youthful patients mentioned above who suffered from attacks whenever the head was touched Be this as it may, the intimate mechanism in respect of facilitation of reflex activity owing to the immediate presence of a pathological condition (tumour, arteriopathic change, an area of sclerosis) remains obscure and this is particularly so where no organic change is in evidence Impairment of transcortical inhibition, which must also in my opinion be postulated, can be nothing else physiologically than failure of one cortical element to inhibit another—a state of affairs the "extreme likelihood" of the occurrence of which is assumed by Sherrington for various fields of cortical action When we speak of the "involuntary" movements of Jacksonian epilepsy we can mean little else than that they cannot be transcortically prevented In accordance with principles suggested for consideration in my previous lecture, it is not necessary to seek an objective lesion actually in or at the "centre" for the reflex arcs concerned the defective inhibition may conceivably be represented by change at some wide region or in some cellular layer remote enough from the spot where they are in action

OCCURRENCE OF TYPHOID-PARATYPHOID BACILLI IN SEWAGE

SOME FURTHER OBSERVATIONS

BY

R. S. BRUCE, M.B., D.P.H.,

AND

H. J. GIBSON, M.B., D.P.H.

(From the Department of Bacteriology, Edinburgh University.)

THE problem of the atypical mild or abortive case of enteric fever is one to which the attention of all concerned with the public health is being directed. Infections of the paratyphoid type may be extraordinarily protean in their manifestations, and it is a matter for speculation at the present time to what extent this disease is accountable for mild illness of short duration lacking all those grave features which have hitherto characterized classical enteric fever. Diagnosis of many cases ultimately recognized to be paratyphoid infection has been made only after repeated bacteriological or serological examinations, such assiduous search being prompted by a definite history of contact with a known case. Improved sanitation has led to a great diminution in the incidence of enteric fever of the severe type, and the danger exists of assuming that the disease is no longer a major factor to be reckoned with in public health work. Evidence is accumulating that such a sense of security is not altogether justified.

Scientific approach to the question is, however, difficult. The typhoid carrier rate in the general community affords one method of attack on the problem. This provides an index of the occurrence of the disease, since the danger of contact infection is always present, even when the conditions of sanitation approach the ideal. Among early attempts to arrive at an estimate of the incidence of carriers in the general population may be mentioned that of Minelli (1906),[1] who found one carrier among 250 persons examined in Strasbourg. Chapin (1916)[2] quotes the finding of organisms of the enteric group in the excreta of 3 of 986 healthy inhabitants of Washington, D.C. Welch and others (1925)[3] carried out a systematic examination of 1,076 healthy dairy workers in an area where the incidence of enteric fever had been considerable during the years preceding the examination. In reporting the high carrier rate of 5·1 per cent. they stress the importance of the repeated examination of both urine and faeces. If results had been based on a single examination of faeces alone the incidence would have been only 1 per cent. Bromberg and Comaroff (1929),[4] in a survey of 484 healthy persons in a district of Palestine which had been subject to frequent outbreaks of typhoid fever, found three carriers, giving an incidence of 0·64 per cent.

The figures show marked variation, which doubtless depends largely on the previous incidence of the disease and the thoroughness of the search. Even the lowest figure indicates that any city community in which enteric fever occurs must contain in the aggregate a very considerable number of carriers.

The work of Wilson (1928)[5] in Belfast and Gray (1929)[6] in Edinburgh suggested that examination of sewage might be a source of useful information regarding possible loci of enteric carriers. Wilson was able to demonstrate *B. typhosus* in the sewage of Belfast, and to arrive at a quantitative estimate of its numbers in the combined outfalls immediately before purification treatment commenced. Gray, in 1929, isolated *B. paratyphosus* B from the main sewer of one district of Edinburgh and proceeded to the examination of tributary sewers draining into this main. Positive results were obtained in three of seven such tributaries. It thus appeared that the method might be of value in localizing an infected district. In the absence of known cases in such districts the isolation of the organism from the sewage indicates a very active discharge either from carriers or undiagnosed cases, both of which are of considerable importance from the standpoint of public health.

The intention of the present work was to survey the main sewers of the city of Edinburgh in order to ascertain how far the findings of Gray were generally applicable. By a study of the incidence of enteric infections in the various districts of the city during the five years prior to and including, that during which the work was carried out, an attempt was made to ascertain whether any correlation existed between the localization of cases and the occurrence of specific organisms in the sewage. The examination of a considerable number of samples by different methods of selective culture provided an extended comparison of their sensitiveness, and it was thought that a standard method might be elaborated and suggested for routine use.

Methods

One sample was obtained from each main sewer and cultures were made within three hours of collection of the specimen. Three methods were employed as follows:

1. Direct plating on MacConkey's medium containing both lactose and saccharose (see Gray, 1929).

2. Ten tubes of brilliant green peptone water medium were inoculated each with a large loopful of sewage. The concentrations of brilliant green (Grübler) in these tubes ranged from 1 in 100,000 to 1 in 2,000,000. The peptone water used was standardized to *p*H 6·4. Incubation was for forty-eight hours at 37° C., when one to three loopfuls from each tube were spread on a plate of the lactose saccharose medium referred to above, the amount of the inoculum depending on the growth visible in the peptone water tube.

3. Three plates of the glucose iron bismuth sulphite brilliant green medium, as described by Wilson and Blair (1927),[7] were heavily inoculated, a glass spreader being used to distribute three to five loopfuls of sewage over the surface of each plate. After incubation for forty-eight hours suspicious colonies were subcultured on to MacConkey plates. Pale colonies from the three sets of MacConkey plates were subcultured into tubes of peptone water and incubated for forty-eight hours. At the end of that time tubes showing pigment production indicative of *B. pyocyaneus* or allied types were rejected and the indole test was carried out on the remainder, positive reactors being thus eliminated. The growth from those remaining was subcultured on a coagulated serum medium so that after incubation for forty-eight hours proteolytic organisms could be excluded. Biochemical reactions were then tested by fermentation of glucose, lactose and mannite and formation of H_2S in lead acetate glucose agar. In this way it was possible to select out possible strains of the enteric group from each sample with the use of the minimum of media. Identification was completed by biochemical reactions with a wide range of carbohydrates and the use of a high titre immune agglutinating serum.

Results

In all, 58 samples of sewage were taken, each being from a different main sewer, so that the sewage of the whole city was sampled. Of these, 7 yielded organisms identified as *B. paratyphosus* B Schottmüller by direct agglutination and agglutinin-absorption tests. From 5 of these samples the organism was isolated only by the method of brilliant green enrichment, from 2 cases by Wilson and Blair's method. In no case was a positive result obtained by both methods. The direct plating of the sewage on MacConkey's medium gave negative results throughout.

In the case of the brilliant green enrichment method it was found that the most effective concentrations were 1 in 200,000 to 1 in 400,000. In those tubes to which smaller amounts of the dye had been added coliform bacilli of the *B. lactis aerogenes* type predominated, while higher concentration tended to inhibit growth of all organisms.

The results are perhaps not a true index of the selective properties of Wilson and Blair's medium as it was found that batches made from the same constituents in apparently the same proportions showed great variation. In many cases no growth whatever appeared despite very heavy inoculation. With other batches good growth occurred, and in the two cases where positive results were obtained by this method colonies of *B. paratyphosus* B were numerous.

A further difficulty with this medium was that we were unable to determine with exactitude the typical colony appearances of the enteric organisms. Test plates inoculated respectively with pure cultures of *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B each yielded a variety of colony types; such variations were the cause of some confusion in dealing with the plates inoculated with sewage when subculture on to MacConkey plates of colonies presenting resemblances to these types showed a large number to be lactose fermenters.

Brilliant green enrichment with such a scheme as has been indicated for the further investigation of strains isolated appears to give the most consistent results and it is suggested for use where a single routine method is required. A series of concentrations of the dye ranging from 1 in 125,000 to 1 in 500,000 has been found to be satisfactory. It must be noted, however, that in our work, as in that of Gray (1929), positive results were obtained by other methods when brilliant green enrichment failed. The use of Wilson and Blair's plating method in addition undoubtedly increases the possibility of isolating organisms of the enteric group. Our results suggest that the methods are to some extent complementary in that factors which militate against the success of one do not appear to operate when the other is used.

Discussion

The areas drained by those sewers from which *B. paratyphosus* B was isolated could be divided into two groups. Four sewers yielding positive results were associated with adjoining districts comprising the whole port area of the city (District I). The remaining three drained part of the southern suburban area, the district being again well defined (District II).

By the courtesy of the medical officer of health for Edinburgh the incidence of cases of *B. paratyphosus* B infection in these districts was ascertained for the five-year period 1925–29 inclusive. The total number of cases notified in the city, excluding imported cases and those arising in institutions, was also available for the same period. Cases on diagnosis were, as a rule, removed at once to the City Hospital, so that recognized sufferers from the disease did not contribute to the discharge of organisms in sewage. The total number of cases arising in Districts I and II amounted to 46, while 103 cases had been notified during the same quinquennium for the whole city. Thus some 44·6 per cent. of the city cases occurred in these districts. It must, however, be noted that the population of these areas, as far as could be ascertained from available data, was approximately 30 per cent. of that of the whole city. It will thus be seen that, on a consideration of a prolonged period of time, little correlation is possible between the localization of enteric cases and the presence in the sewage of the specific organism in numbers sufficient to render isolation possible. This lack of correlation was further accentuated when the cases for the four years prior to that during which the examination was made were considered. During 1925–28 inclusive only 18·2 per cent. of the city cases originated in Districts I and II (8 out of 44 cases).

The figures for the year 1929, however, showed a more significant relationship to our findings. During this year 59 cases of *B. paratyphosus* B infection were traceable to infection within the city, and of these 38 appeared in Districts I and II. Thus approximately 30 per cent. of the city population provided 66·4 per cent. of the total number of cases. This would appear to show a marked relationship between the presence of paratyphoid bacilli in sewage and the topographical distribution of the disease.

Taking the finding in the case of each district separately further light was thrown on this subject. District I had an estimated population which was 19 per cent. of that of the whole city, 34 cases of *B. paratyphosus* B infection occurred in this district in 1929, or 57·9 per cent. of the total city cases. District II, on the other hand, representing 11 per cent. of the city population, provided only 6·7 per cent. of the total cases. Thus the two districts, from both of which specific organisms were being discharged in enormous numbers, gave widely divergent results in respect of case incidence.

The explanation of this may be in the difference between social conditions of the two population groups. District I represents a congested tenement area, while District II comprises for the most part a residential suburban area of modern construction. Probably the best index available for the expression of this factor is the population density. The most recent figures available are those of the annual report by the medical officer of health for the city for 1928. District I showed a mean density of approximately 48·8 persons per acre subdivisions varying from 35·4 to 98·1, while that for District II was 5·8 persons per acre.

It seems probable that the finding of organisms of the enteric group in sewage indicates the presence of a potential or active source of infection, but that under conditions of life as found in an upper-class residential district the habits of the people are such that spread from such foci does not arise. In an overcrowded tenement area, however, the presence of a concentration of carriers, as indicated by the possibility of demonstrating the organism in sewage, is reflected in a high incidence of cases.

The sewer from which Gray isolated the organism in 1928 drained a district in which an outbreak of the disease had occurred in 1927. At the time of the present work (1929) this sewer yielded negative results. In the same way we were unable to demonstrate the specific organism in the sewage of other districts in which outbreaks of enteric fever had occurred during previous years. These findings would suggest that the permanent or chronic carriers which might be expected to result from such outbreaks are not sufficient to account for the massive discharge necessary to ensure isolation of the organism from a main sewer.

If any conclusion is possible from the present work it is that the presence of organisms of the enteric group in sewage indicates a concentration of missed cases, convalescents, and transient contact carriers in the general population. Such a circumstance may be found in association with, or immediately following, an outbreak of the disease. From a consideration of an upper-class suburban district it is suggested that such a focus may exist without any *frank outbreak* of the disease at the time of the examination or preceding it.

Summary

1. A series of 57 specimens of sewage, which included samples from all main sewers of a city, has been examined with a view to the isolation of organisms of the enteric group.

2. By the use of three different methods of selective culture *B. paratyphosus* B Schottmuller was isolated from seven samples.

3. A simple routine method for isolating enteric organisms from sewage is indicated.

4. A comparison has been made between the incidence of *B. paratyphosus* B infection in areas drained by sewers giving positive results, and in the city as a whole.

We wish to acknowledge our indebtedness to Professor T. J. Mackie for the interest he has taken in this work, also to those of the sanitary staff of the city who have assisted in obtaining the necessary sewage samples.

FOOD POISONING DUE TO EGGS

BY

W. M. SCOTT, M.D.,

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH

ONE habitually regards an egg as one of the safest and most wholesome forms of food. When the Three Musketeers had just escaped by a chance from death by the poisoned wine arranged for them by Lady Clarick, they sought safety in plain boiled eggs, and water drawn by Athos in person from the public fountain. But there is strong reason to believe that this innocence of the egg is, after all, only relative, and that, in fact, eggs are responsible for many cases of food poisoning which remain mysterious—that is, cases of severe or fatal gastro-enteritis due to salmonella infection in which none of the usually suspect articles can be incriminated. During the last three years there have been quite a number of instances of this kind, affecting both single individuals and groups of people. It has never been possible to bring absolute

proof, for this, some part of the infected egg must remain for examination and yield the specific salmonella in culture But circumstantial evidence has been so strong in most of those instances that the absolute proof becomes quite unnecessary

Let me briefly describe a few examples The first that came my way was in 1926, a solitary case, a young woman in Stepney, who died with an *aertrycke* septicaemia after thirteen days of gastro-enteritis, which began six hours after eating a fried duck's egg All the other articles of food and drink which could possibly have conveyed the infection had been shared with impunity by others In 1927 a trifle was consumed by ten out of a party of twelve in Darlington All the ten were seriously ill owing to an *aertrycke* infection, while the two who had had no trifle but had shared in all the other food remained well The cream of the trifle had been prepared by whipping the white of ducks' eggs none of it remained for examination, but another trifle made at the same time by the same person and of the same composition was found free from infection The only components not common to the two trifles were the ducks' eggs, which were whipped in separate batches

A custard made with ducks' eggs was responsible for a most violent gastro-enteritis in Portslade in the same year A family of three adults who finished the dish were so ill that they lay unable to call for help for two days one of them died with an *aertrycke* septicaemia, as usual, none of the custard could be obtained for examination

The largest outbreak in which egg is suspected occurred in 1927, in the neighbourhood of Bath It involved over 300 persons, with one death, the vehicle being ice-cream Here again, though proof is not quite complete, it seems certain that a duck's egg, infected with *B aertrycke* and used in the confection of the ice-cream, was responsible, the ice-cream contained abundant *B aertrycke*, while none of the other ingredients of the mixture, except the eggs, could be suspected

Altogether in the last three years or so there have been at least seven outbreaks in this country in which circumstantial evidence points to eggs as the cause—in each instance to ducks' eggs, there have been, in addition numerous solitary cases, often fatal, in which no particular article of food was suspected except, as I shall suggest, an egg

When I came to look into the matter of food poisoning from eggs, I found to my surprise that there was quite a literature on the subject of which I had been totally ignorant My colleague the late Dr Spencer Low had collected many references which he put at my disposal, and, in particular, he passed to me a monograph, published in 1906 in Paris by A Lecoq, on poisoning caused by whipped cream In this monograph Lecoq shows that the poisoning properties of such creams prepared by mixing cream, gelatin, and white of egg have long been known He shows that these poisonous properties appear most commonly in summer, that they are not due to metallic poisons—copper, tin, or lead dissolved from the mixing utensils—as it was once the fashion to suppose, nor are they due to putrefactive products, ptomaines, tyrotoxin, etc—the later fashionable hypothesis—but that they are due to bacterial infection of the egg albumen The method of infection which Lecoq thinks most likely is introduction of infective material into the oviduct of the hen or duck during copulation, with infection of the albumen as it is being deposited round the yolk, he recites numerous observations of foreign bodies—straws, seeds, stones, etc—found embedded in eggs and obviously introduced in this manner, and explains the greater frequency of infection of ducks' eggs by the fact that ducks "practise their amours" in ponds and ditches, where specific contamination of the water may easily be present

Another method of infection of the egg, however, is possible, and was suggested by Spencer Low in an investigation which he conducted on a food poisoning outbreak in 1913 in the Yeadon district of Yorkshire, due to cream buns Low proved conclusively that the infecting component must have been present in one or more of a batch of cooking eggs, the white of which was used to make whipped cream He discussed Lecoq's hypothesis and suggested that infection of the ovary, oviduct, and egg with salmonella could take place as part of a general infection of the bird, such as has been assumed to occur in parrot subjects of psittacosis As is now well known, the salmonella infections peculiar to fowls—namely, *B pullorum*, *B gallinarum*, and *B sanguinarium*—are, in fact, associated with specific infection of the egg though there is no case recorded where infection with these salmonellas has given rise to food poisoning in man On the other hand, Rettger and Scoville[1] in 1920 described an epizootic among ducklings resembling the *pullorum* outbreaks in chicks with transmission due to infection of the egg They isolated from the ovary of a duck among the suspected flock a salmonella which they called *B anatum*, but which is, in fact, probably *B aertrycke*

I intended to demonstrate this method of egg infection by direct experiment, but found it impossible to get ducks to lay eggs in the animal house available I feel sure it can be done under suitable conditions, and I recommend the experiment to those who have facilities

There is still another way in which eggs may become infected with a salmonella, and it is one which is easy to show experimentally Eggs, both of ducks and of hens, kept dipped in cultures of *B aertrycke* can become infected within a few days If the culture is simply allowed to dry on, infection fails, part of the shell must remain moistened for penetration to occur At first *B aertrycke* multiply rather slowly in the egg and special cultural measures are necessary to detect them, one supposes that the strong bactericidal action of fresh egg albumen is the explanation But as the infected egg becomes staler, say in a fortnight or so at room temperature, the salmonella multiplies rapidly and an egg then may come to represent an enormous dose, a loopful of albumen or yolk—for both seem to become infected—yielding countless colonies of *B aertrycke* Such an egg may appear to the sense of smell as no more than slightly stale, and might certainly be regarded by the less discriminating cook as usable

All eggs are not readily infected in this manner Some can be dipped in a culture for as long as six weeks and remain either sterile or with only the common non-lacto-fermenting bacillus which is characteristic of staleness in eggs and is non-pathogenic one out of fifteen was of this kind, resistant to the specific penetration

The question now arises, Can such infection of eggs occur in ordinary farming practice? Here again I regret to say that I have made no direct experiment, such as leaving eggs in an infected duck pen All I can say is that ducks fed with cultures of *B aertrycke* or *B enteritidis* continued to discharge these salmonellas in enormous numbers in their dejecta for at least a week During this period their bedding, allowed to remain moist, became the equivalent of a rich culture of the specific bacilli, so that an egg left in it might as readily be infected as in the more artificial conditions Domestic ducks are well known to lay in the most casual fashion, dropping eggs often in the water of the ponds and ditches in which they feed, and such eggs may be gathered and marketed after specific contamination has occurred In the case of fowls which lay in dry surroundings, this method of infection probably occurs rarely, if ever, and to account for a salmonella infection of a hen's egg one must bring in one of the other two methods, these, though possible are as a matter of fact, much less likely to occur in the hen than in the duck The duck's egg, however, has quite definite opportunities of infection in all three ways, and care should be taken in using them in any manner in which thorough cooking is not involved—for example in the making of creams, ices custards, or even lightly boiled That the risk is comparatively remote is not to be doubted it is hard to estimate what proportion of the many millions of eggs consumed each day in this country consist of ducks' eggs but it must at least, be many thousands while food poisoning from eggs is so comparatively rare that it has hardly hitherto been regarded seriously I am inclined however, to think that salmonella infections from eggs are, in reality a little more common The spectacular instances, of course, are rare, but there are many a tacks

of gastro-enteritis which are never investigated When food poisoning occurs, the usual history is that several people are attacked nearly simultaneously by severe sickness, they compare notes and decide that a certain article of food or drink or a certain dish must have been the cause Generally speaking the suspicion is found on inquiry to be justified, and, when specimens are available for bacteriological examination, it is usually possible to complete the proof by isolating one of the salmonella types both from the suspected food and from the sufferers But not uncommonly acute gastro-enteritis attacks a single individual in a household, and suspicion is not directed to food or drink as the cause, more especially as it often happens that meals have all been in common and the commensals escape illness Such cases may evade investigation entirely Occasionally, however, the person so attacked may die after an illness lasting from one to fifteen days and may become the subject of a coroner's inquest and a pathological examination The result may be that a salmonella is found in the alimentary canal and throughout the organs, exactly as in the fatal cases in a larger food-poisoning outbreak The source of infection in these solitary fatal cases almost always remains undiscovered, the sufferer may be too ill to be questioned, or suspicion may not even arise till after the fatal ending and the bacteriological report What I should like to suggest is that the cause of some of these solitary cases is an infected egg Obviously the solitary nature of the infection, no one else suffering in the family or among those sharing the same meals, indicates an unshared dish as the vehicle an egg is one of the commonest and most conspicuously unshared of such unshared dishes in ordinary life, and in spite of its notorious innocence should not escape suspicion

THE TREATMENT OF VARICOSE VEINS BY INJECTION

BY

NOEL SCOTT, M R C S, L R C P,

SURGICAL ASSISTANT, OUT PATIENT DEPARTMENT, ROYAL WATERLOO HOSPITAL

THE treatment of varicose veins by injection originated over seventy-five years ago, but, although Professor Sicard of Paris treated a large number of patients by this method from 1915 onwards, it was not generally recognized in Great Britain until a few years ago It was introduced at the Waterloo Hospital in 1925 by Mr Rodney Maingot as a routine treatment, in that year the Varicose Vein Clinic was inaugurated, and the number of cases has steadily increased until we are now dealing with some thousands a year

We use an ordinary 5 c cm Record syringe with a No 16 needle As we treat a large number of patients in each clinic it is impossible to sterilize the syringe and needle by boiling After each injection the syringes and needles are washed out with distilled water and are placed in spirit, they are then ready for the next patient

The ideal position of the patient is prone upon a couch, the veins are collapsed and therefore more easily injected This is only possible, however, when the veins are large and remain very apparent even when the patient is lying down In most cases the patient is treated while sitting on an ordinary chair But in a certain number of cases neither of these courses is practicable, and it is then necessary for the patient to stand on a low stool with the weight of the body on the affected limb

The skin over the vein to be injected is sterilized with spirit It is not desirable to use a tourniquet because it produces venous engorgement, it is difficult to manage single-handed and it causes considerable pain to the patient

Three solutions are in general use at present—namely, (1) quinine urethane (quinine bihydrochloride 4 grams, urethane 2 grams, and distilled water to 30 c cm), (2) lithium salicylate 30 per cent with tutocaine 0 75 per cent and (3) sodium chloride 20 per cent with tutocaine 0 75 per cent The one in most use, as far as we are concerned, is the lithium preparation, it sclerosses well, and produces no symptoms The only practical objection to its use is that it does not keep well, as a rule after about ten days it starts to turn brown from exposure to light and heat, and has to be thrown away The sodium chloride preparation is very good for the injection of small veins, especially if they are thin-walled and the skin over them is atrophic, in these cases it is impossible to inject the other solutions, which will not be tolerated It should, however, never be used in large healthy veins From the point of view of thrombosis quinine urethane is the best preparation, but many patients cannot tolerate it, even in the smallest doses Any dose over 2 c cm is always liable to give rise to buzzing in the ears, flushes, headaches, and hypogastric pains, these occur almost immediately after injection, and may even lead to loss of consciousness Although the patient recovers quickly and the symptoms rapidly disappear they give rise to a certain amount of apprehension as to future treatment, and are also very undesirable when there are other patients in the room For this reason we have abandoned the use of quinine urethane except in cases of the "twin injection," with which I shall deal later on

The dosage is important The usual dose of lithium and sodium chloride is 4 c cm and of quinine urethane 2 c cm It is never advisable to give more than 2 c cm of quinine at one sitting, and at first 1 c cm of any solution is the most that should ever be injected It is important to see how the patient reacts, by starting with small doses, and thereby minimizing the pain, confidence is won, and larger doses can be reached without any untoward effect Injection of the full dose of 4 c cm at the first sitting might produce pain and cramp, and, in a certain number of cases, cause the patient to cease attending for further treatment

In injecting the solution into the vein it is advisable as a rule to work from below upwards The skin is sterilized, the selected vein is steadied by the left hand, and the needle is then inserted obliquely from below upwards in the line of the vein When it is felt that the vein has been entered, the plunger of the syringe is cautiously pulled out, and, if the needle is in the vein, blood will flow easily into the syringe Injection can then be performed If the operator is uncertain whether the needle is in the vein he should repeat the procedure of pulling out the plunger If an bubbles appear it is a sign that the needle has gone through the vein or that its point lies in the subcutaneous tissues He must then either alter the position of his needle until he has successfully secured re-entry, or, in any case of doubt withdraw it and try again It is always advisable to inject in one spot, if possible, and small doses in multiple punctures should be avoided During injection the point of the needle must be held perfectly steady, since the slightest deviation will probably cause complete penetration of the vein and the subsequent discharge of the solution into the surrounding tissues The solution should be injected slowly and steadily When the injection has been completed a pad of wool should be held over the site during withdrawal of the needle to prevent the leakage of blood The limb is then raised, the site of injection is wiped dry with spirit on a small piece of cotton-wool, and either ordinary plaster or "elastoplast" is fixed to the spot There is no necessity for the patient to lie up after the injection There may be a certain amount of pain or cramp persisting for a few minutes, but as a general rule patients can walk away immediately after the treatment

Immediate Local Effects—These are as follows (1) the vein may collapse or dilate after injection, (2) the vein may become hard at once, (3) there may be severe pain at the time of injection, (4) there may be external haemorrhage and/or subcutaneous bruising, (5) there may be no change, (6) thrombosis may occur and a satisfactory result ensue Thrombosis usually takes place in from six to twenty four hours

Immediate General Effects—Shock may occur, also collapse and fainting In cases of quinine injection there may be buzzing of the ears, headache, etc

Late Local Effects.—These consist principally of ecchymoses and gangrene of the vein, and ulcer of these, the most common by far is the 'injection ulcer' which is due in most cases to the deposition of the solution in the tissues round the vein. It is serious and painful, and four to six months elapse before a cure is effected. No case of injection ulcer should ever occur, it is in all cases due to carelessness in the administration of the injection. In most cases the operator has entered the vein successfully, but in the course of injection, through a momentary unsteadiness or movement of the patient, the vein has been penetrated and the solution deposited in the surrounding tissues. This should never happen if the precaution of withdrawing the plunger of the syringe in moments of doubt has been observed. The last late local effect is the complete thrombosis and gradual elimination of the vein. This takes some three to twelve months to occur, the vein gradually becoming hard and cord like to the touch. Over the bony surfaces the process is slow, but in the thigh it is much quicker, and as a general rule it may be stated that the vein should be practically obliterated in twelve months time.

There is only one important late general effect—pulmonary embolism. This is a very rare occurrence in some ten thousand cases treated at the Waterloo Hospital there has so far been no record of such a sequel. Yet there is a chance that this may occur since there are records in the medical literature of many cases.

In those cases which I have indicated above where no change takes place after injection there is one infallible method of treatment which is known as the 'twin injection.' It is generally necessary to make use of this when the veins are very large with extensive varicosity. The selected vein receives simultaneous injections of 4 c.cm. of lithium and 2 c.cm. of quinine urethane solution, the sites of injection being 3 to 5 inches apart. It is possible to do this single-handed by injecting the lithium first and the quinine immediately afterwards, but in actual practice it is much more satisfactory to have assistance for one of the injections. The quinine must never be injected first because, if this is done, when the lithium is being injected and the barrel of the syringe is being pulled out, there is a great likelihood of withdrawing some of the quinine from the vein, and this immediately causes clotting in the syringe. This 'twin injection' invariably causes clotting, but it must be emphasized again that it should not be employed unless the veins are very large.

Other solutions have been tried by us but have been abandoned for various reasons. Pure carbolic (98 per cent.) is a sticky solution, it spoils the syringe, the dose of 1–3 m. is difficult to assess owing to the stickiness, and it causes perivenitis, and, occasionally, haematuria. Alcohol (50–100 per cent.) in a dose of 1–5 m. is too painful. Sodium citrate (20–50 per cent.) has been given in doses of 0·5 to 4 c.cm., but the results proved unreliable. Sodium salicylate (20–50 per cent.) in a dose of 1–4 m. was also unreliable, about 60 per cent. of results are good if this solution is used exclusively.

In a number of hospital cases there is severe varicose vein ulceration. If the ulcer is very large the limb should always be x-rayed in order to determine whether or not there is any periostitis. Should the bone be involved the ulcer will naturally take longer to heal under treatment. In all cases a Wassermann test should be performed.

Treatment of Varicose Ulcer.

If no veins are visible Unna's paste bandage should be applied once a week. Where veins are present they should be injected weekly in addition to the use of the bandage. In severe cases the base of the ulcer should be injected with quinine urethane. Two sites are selected and into each 2–5 m. of quinine is injected at an oblique angle, the one from above the other from below. In this way a small "island" of the ulcer is cut off and heals. Our method is to attack and heal a series of "islands" until the entire surface of the ulcer is healed. In very small ulcers 2½ per cent. tannic acid solution on lint is applied to the part every four hours. This forms a crust over the surface of the ulcer and stimulates healing under the crust.

The treatment of an "injection ulcer" is as follows. For the first few days hot fomentations are applied. They are followed by pure hydrogen peroxide, and then by the application of calamine lotion. These ulcers are very painful, and the patient should be warned that a cure will not occur in less than three to six months.

The contraindications to treatment are five in number. (1) Pregnancy, the veins will probably disappear after confinement, and treatment should never be given during pregnancy. (2) Deep thrombosis. (3) Acute superficial thrombo-phlebitis. At least three months must be allowed to elapse from the time that all inflammation has disappeared before treatment is attempted. (4) Advanced heart, lung or kidney disease, diabetes, and high blood pressure. (5) If the varicose vein ulcer is very septic it is advisable to clean it up first before injection treatment is attempted.

We have found from experience that the following rules are highly important, if a satisfactory result is to be obtained in the treatment of varicose veins by this method.

Rules for Injection.

1. Never inject more than 1 c.cm. at the first sitting.
2. Never inject more than 6 c.cm. at the one sitting in one limb.
3. Never inject more than 2 c.cm. of quinine urethane at the one sitting.
4. Never inject more than 4 c.cm. of lithium or sodium chloride.
5. Inject weekly.
6. Avoid small doses and multiple punctures.
7. Work from below upwards.
8. Never inject if the veins are painful or if after the time of the introduction of the solution there is bulging of the vein.

Remarks.

An injection ulcer appears in about 1 per cent. of all cases. With quinine or lithium about 20 per cent. of cases will not "take." These 20 per cent. of cases will "take" with the twin injection. For a few days following the injection the limb may be painful, and patients should be warned of this; they should also be warned of the local and general effects. When injection is performed near the ankle some oedema of the feet nearly always results. The final results may be very good but varicose veins may form in other parts of the limb and even veins which have thrombosed as a result of the treatment may recanalize.

Provided that there are no complications or contraindications there are no cases which will not with care and time and judgement respond satisfactorily to treatment by the injection of suitable sclerosing solutions.

INTRAVENOUS SCLEROSING SOLUTIONS

BY

T. HENRY TREVES BARBER, M.D., B.Sc.

It has frequently been stated that the nature of the clot, subsequent to sclerosing injections, is dependent upon the chemical used for the injection, some forming a soft friable clot, others a firm adherent one. As a matter of fact the consistency of the clot is entirely independent of the drug injected.

To elucidate this important question the following experiments have been made. They prove that (1) *the injected solution has but a very fugitive effect upon the endothelium* of the injected vein. (2) *no primary formation of a clot* is possible from the blood itself with the solutions and doses used, since the normal clotting of the blood (*in vitro*) is retarded by its admixture with them.

Withdraw from a varicose vein 2 or 3 c.cm. of blood and pour into a test tube. At first it is dark red. Leave the needle in place, adjust it to a syringe charged with 5 c.cm. of a 20 per cent. solution of NaCl and inject. When the injection is about half way done aspirate some of the blood into the syringe. At the end of the injection the piston is immediately and slowly withdrawn. Brilliant scarlet blood flows into the syringe for fourteen to forty five seconds according to the rate of the circulation in the selected vein (rapid change of colour is found in those vessels having a sufficient circulation). In all cases however within a full minute of terminating the injection the blood appears to have resumed its normal colour.

Withdraw 2 c.cm. of this mixed blood and pour into another test tube, B. It is found that this blood remains a bright scarlet for many hours and also remains liquid for some hours after the normal blood has not only coagulated but a large clot has formed.

These reactions are, of course, more marked when a considerable amount of the solution is still in the blood (large dilated ampullae) and when it is withdrawn immediately after the injection has been given. The withdrawal of this amount of medicated blood has not—in my experience in over 20 cases taken at random—prevented the veins from reacting and being cured. Further experiments might be undertaken with other drugs, so as to discover whether the desired obliteration could be accomplished by injecting followed by the immediate withdrawal of as much of the drug as possible, so that more active doses might be used and idiosyncrasy avoided.

Deductions. (1) The solution remains but for a very brief period *in loco*. (2) Addition of NaCl solutions (20 per cent.) to blood withdrawn from a vein retards its clotting *in vitro*.

Since the solution remains in the vein for something under one minute, and as we know that for about twelve hours no naked-eye or microscopical changes are discernible in the vessel walls, after which time, however, changes begin and are progressive to the formation of a blood clot, it seems only logical to deduce that this clot is the after-result of a momentary, severe, but purely local chemical reaction on the endothelium at the time of the injection. The physical properties of this clot are most likely due to the extent and degree of the reaction from the sclerosing effect of the solution, and whether or not some degree of infection was present in the vein at the time. If the vein is free from active infection and the reaction severe, the clot will be hard, adherent, and possibly extensive. Should there be any infection present the clot might soften, break down, and cause an embolism at some future date. All cases of emboli, if they are ever to be directly attributed to sclerosing solutions, as being their sole origin, must occur either during the injection itself or at least a very short time after it. A few such cases have been reported from time to time with quinine and urethane, and also with sodium salicylate, the recorded symptoms are suggestive of some embolic complication, but of a transitory nature, and the patients recover very rapidly. Other cases are on record where huge doses of drugs have been injected, doses that converted an otherwise non-productive infarct substance into an infarct-forming one, causing immediate clotting of the blood *in situ*. It is not remarkable that in such circumstances fatal cases have been recorded.

As already stated, NaCl retards coagulation, it is improbable that at any time, in normal conditions, this solution is ever capable of giving rise to an embolism. On the other hand, it has frequently been accused of always causing pain, and often very severe reactions. It sometimes causes a very intense reaction, so may quinine and sodium salicylate, but under these conditions (due entirely to the individual) there is little left to choose between them as regards the intensity of the pain and discomfort experienced by the patients, the end-results will, however, generally be excellent.

Colt, using sodium salicylate with 10 per cent. NaCl, stated some time ago that he believed it was better to use large quantities of medium strength solutions than small concentrated ones, the theory seems to be borne out by the above experiments. Gillespie and Strobel state that they, too, use large doses of 20 per cent. NaCl—10 c.cm. for one injection, up to 20 or 30 c.cm. at one time, or with 5 or 10 c.cm. three or four injections can be made at one sitting. They claim that with this solution a more adherent and extensive thrombosis, and a better end-result, is obtained than with other sclerosing solutions.

Why are NaCl solutions the most active in this form of treatment? Probably because they have a greater destructive power upon the endothelium, and because it is possible to give such large doses that the chemical effect upon the vessel wall is proportionately of longer duration than it is with other drugs used in small but concentrated solution. The reaction on the vessel is greater, more lasting and probably more penetrating, which may account in part for the transitory pain which is frequently, but not invariably, encountered. These solutions of NaCl are not necessarily painful, but only so under certain conditions due to the pathological state of the veins themselves. At all events, it may be affirmed that they retard clotting of the blood, and that therefore they are incapable of giving rise in the ordinary way to any thrombosis, either at the time of injection or subsequently; they are probably the most effectual and the safest to use at present, and will remain such until the ideal solution has been discovered.

In conclusion, mention might be made of a new and very interesting sclerosing agent—namely, sodium morrhuate, as recommended by Higgins and Kittle (*Lancet*, January 11th, 1930). I have used it in a small number of cases with good results. If time and experiments should prove it to be always reliable and safe, it will probably supersede all other sclerosing solutions now in general use.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE BRONCHITIS WITH VAGINAL BLEEDING AND ACUTE ABDOMINAL PAIN

THE following case, in which an attack of acute bronchitis with abdominal pain and vaginal bleeding simulated a ruptured ectopic pregnancy, is perhaps of sufficient interest for publication. The occurrence of bleeding per vaginam from the uterus or adnexa, when the origin cannot clinically be determined, is a puzzling feature in questions of abdominal diagnosis. Cases of such haemorrhage depending on general or local vascular disturbance have long been recognized and cannot be rare (vide Kelly's *Gynaecology*, p. 708), and no doubt many of the elect have from time to time been deceived.

A married woman, aged 40, was admitted to the Withington Hospital on October 30th, 1929, as a case of ruptured ectopic pregnancy.

Previous Medical History.—She had had two children, the second being born fifteen months previously. There was no history of abortions, and the periods were regular. No leucorrhoea was present.

Present Illness.—This started with acute abdominal pain, which was most marked in the lower abdomen, and especially on the left side. Lower abdominal hyperaesthesia and tenderness were present. Rigidity was not great, owing to a lax and obese abdominal wall. Before admission she had lost per vaginam three-quarters of a pint of blood. The temperature was 98.6°, the pulse 90, and the respirations 28.

Bimanual Examination.—The cervix was found to be closed, the uterus and adnexa were normal. A slight bogginess was felt on the right side, possibly due to constipation, since it disappeared later after an enema. Blood was deposited on the examining finger.

Lungs.—The acute bronchitis was not well established till later, but rales and rhonchi were heard in both lungs. The respiration was hurried, the facies was anxious and slightly cyanotic.

Progress.—Expectant treatment was adopted, but solely at the time on account of the lung condition. On an hourly pulse and respiration chart the pulse rate was never above 100, while the respiratory rate increased in a few hours to 40 per minute. The temperature never rose above normal. There was no more vaginal bleeding, and, following appropriate treatment, the chest condition quieted down within twenty-four hours. She was discharged apparently perfectly well ten days later.

This case clinically was without doubt one of acute bronchitis, as is especially evident in retrospect. No pelvic lesion could be demonstrated to account for the vaginal bleeding. With subsidence of the chest signs the patient improved rapidly, and on discharge was apparently perfectly well. I feel certain that laparotomy would have shown a normal uterus and adnexa.

The bleeding was due presumably to vascular congestion consequent upon the acute bronchitis, for on admission the patient was slightly cyanotic. The possibility of an adnexal tuberculous process could not be excluded, as the patient had been in a sanatorium for tuberculosis for three weeks seven years before, but this condition had apparently cleared up completely. The only reason why laparotomy was not performed was on account of the chest condition, as the diagnosis of ruptured ectopic pregnancy was foremost in our minds.

W. C. D. WALMSLEY,
Assistant Medical Officer, Withington Hospital, West Didsbury, Manchester.

ANOTHER DISEASE CAUSED BY WOMEN'S FASHIONS

DURING the last year or so I have seen an increasing number of cases of the condition about to be described among women coming under my care for other reasons, and in three or four cases I have actually been consulted with regard to the condition itself

It apparently only occurs in women of 35 years or more who have bobbed or shingled hair, and who also have the coarse, greasy type of skin with patulous sebaceous follicles It consists of a pigmented band—more or less continuous according to the shape of the head—lying horizontally across the upper part of the forehead generally about half an inch in width across the front, but usually wider and less regular at the temples In summer, and at a distance, the effect might be mistaken for that of the natural contrast between sunburnt skin and skin protected by the hat, but on close examination the lesion is seen to be composed of telangiectases, a marked deepening of the colour at the folds of the natural fine wrinkling of the skin and pigmentation of a yellowish brown colour arranged sometimes in a rough network and sometimes collected into freckles of irregular size and shape

The lesion does not disappear in winter, and in some cases forms a definite and conspicuous disfigurement It is, moreover, very difficult to remove Sufficiently vigorous application of CO_2 snow removes some of the pigmentation in rather a patchy manner and the larger telangiectases can be dealt with by electrolysis, but the lesion somehow or other seems to remain visible

The first time I noticed the condition I thought it was a limited manifestation of Civatte's poikilodermia reticularis, which it resembles very closely, but I soon had an opportunity of observing its coincidence with the red groove formed on a patient's forehead by the recent pressure of a hatband

Women, owing to the carriage of the head differing from that of men, wear their hats further back—they present in relation to their hatbands by the vertex, as opposed to men, who present by the brow The vertex, as the obstetrician knows, subtends a shape admirably adapted to slip out of such things as hatbands With the added mechanical disadvantage of the hair not being anchored at its distal end it has been necessary for hats to fit more tightly than ever

It seems probable that the seborrhoeic condition of the forehead may also have a mechanical influence in the matter For reasons which will be obvious I have not been able to study the condition histologically and I confine myself to drawing attention to the condition and its immediate cause

J H TWISTON DAVIES, M B,
Dermatologist, Royal Sussex County Hospital.

SPRUE TREATED WITH INTRAVENOUS INJECTIONS OF CALCIUM CHLORIDE

THE following clinical details of a case of sprue are interesting in view of the fact that this disease is very rare in Costa Rica, and there do not seem to be any published reports on this system of treatment

A coffee planter from Costa Rica aged 69 was first seen in August 1928 with a two months' history of loose frothy clay coloured motions associated with loss of weight and anaemia A diagnosis of sprue was made

During the subsequent eleven months some portion of which was spent in hospital he received treatment on the usual lines He was dieted strictly calcium was given both as the lactate and also in a proprietary preparation liver subcutaneous iron and arsenic injections strawberries and Batavia powder were also tried The latter controlled the diarrhoea but did not appear to affect the course of the disease and his condition deteriorated The weight dropped from his usual 10 st 6 lb to 8 st 13 lb and loss of appetite and weakness were marked In February 1929 he was admitted to hospital and put on 2 lb in weight but he was discharged some weeks later very little better

In July 1929 intravenous calcium treatment was started in conjunction with parathyroid extract but the parathyroid was omitted later as it appeared to have no effect The series of injections commenced with an initial dose of 1 c.cm which was gradually increased to 3 c.cm at intervals at first of three days which were increased to a week or longer as the patient's condition improved A total of twenty five injections was given

The general condition of the patient greatly improved His weight has increased from 9 st 1 lb to 10 st 9 lb His appetite is better and he has much more energy The looseness of the bowels has not disappeared there are still on an average or two motions daily as contrasted with the daily two to three before the intravenous therapy was employed

As an experiment for a fortnight the treatment was omitted and he was given instead 10 grains of calcium chloride three times daily No effect was produced other than heartburn and loss of appetite and the patient did not experience that sense of well being and energy which he always noticed after the intravenous administration There did now appear to be ankle oedema to the treatment For a few moments after the injection there was a sense of constriction in the throat but this soon passed off and caused no inconvenience

Lloyd[1] reports that sino-auricular heart block has been produced by 4 c.cm of 10 per cent calcium chloride solution injected intravenously, but that on the other hand, 50 c.cm of 1 per cent calcium chloride have been injected without noticeable effect Dutton recommends an initial dose of 1 grain in intravenous calcium administration for any purpose In the present case a 2 per cent solution was used

St. Leonards-on-Sea W. COVEY, M.B., B.Ch. Oxon.

Reports of Societies

SPRUE

AT the meeting of the Royal Society of Tropical Medicine and Hygiene on June 19th, with Dr. G. CARMICHAEL LOW in the chair, a paper on the applied pathology biochemistry, and treatment of sprue was read by Dr. N. HAMILTON FAIRLEY

Dr. Fairley conceived of sprue as essentially an alimentary disease, the clinical features and pathological haemolytic and biochemical findings being explained in terms of the resulting dysfunction of the gastro-intestine The pathological lesions, which were primarily inflammatory and secondarily atrophic, had a notoriously patchy distribution, and in the later stages might implicate the whole tract Involvement of the stomach was indicated by the frequency of defective acid secretion and as in pernicious anaemia, deranged gastric secretion probably underlay the megaloblastic hyperplasia of the marrow and the megalocytic anaemia so characteristic of sprue *The aplasia which the megaloblastic marrow underwent in* sprue resulted from malnutrition, and was analogous to the corresponding changes produced in the normal megaloblastic marrow of pigeons undergoing starvation Investigations on the blood chemistry of sprue showed that total as well as the ionic serum calcium was frequently reduced, and also that this reduction was not accompanied by an increase in the inorganic phosphorus The essential principles in the treatment of sprue might be summarized as (1) alimentary rest, (2) restoration of the blood to a normal condition, (3) reinforcement of lowered blood calcium and defective HCl secretion In sprue the starchy foods and the disaccharides in the gut gave rise to acid fermentation, while fat was poorly absorbed Of the fundamental foodstuffs, protein, especially in the form of minced underdone red meat, was well tolerated leaving little residue, and the author submitted that the most rational method of obtaining alimentary rest under such conditions was by the administration of a high protein low fat, low carbohydrate adequate vitamin diet *The effects of a high protein diet were very obvious* clinically since the stools showed a fall in their fat content became neutral or alkaline in reaction rapidly decreased in bulk and number, while abdominal distension and intestinal flatulence disappeared In all cases of megalocytic anaemia liver extract in full dosage was administered during a steady improvement in red cell count and percentage of haemoglobin followed Large transfusions of whole blood in cases proportional to the gravity of the anaemia response was elicited

Colonel F. P. MACKIE, I.M.S., believed sprue to be a disease *sui generis* although it was fundamentally an infective disease though what the specific infective agent was

Reviews

GYNAECOLOGICAL TECHNIQUE

IN his *Gynecologic Technic*,[1] Professor THOMAS H CHERRY has given a very full account of the technique which he has evolved in his gynaecological work in New York. Such a book has of necessity a limited appeal, for its main interest is for those who have the opportunity of watching and performing the operations he describes, but we know of few such works in which the steps of operative treatment are given with so much careful precision. For the English reader there lies a certain difficulty in the nomenclature of operations and instruments. He will be at a loss to identify such clamps as the Allis and the Oehsner, but with the help of the illustrations, mostly drawn by the author and all admirably clear, it is easy for anyone with a rudimentary knowledge of gynaecology to follow the steps of the operations. The chapter on radium, which in a work of this kind is naturally rather meagre, though sound and full of interest, follows the technique of the Stockholm school. In the treatment of cervical cancer Professor Cherry has discarded the Wertheim operation and replaced it with treatment by radium. He looks with disfavour upon the use of radium in cases of fibromyomata of the uterus, although in this country the method has had some success. An excellent feature of the book is the space given to the medical treatment of gynaecological conditions. Although we do not altogether share Professor Cherry's faith in such remedies as the injection of mammary gland, corpus luteum, and extract of ovary at the climacteric, in our opinion there is a great need for further teaching in the therapeutics of gynaecology. This book recognizes also the outstanding importance of treatment before and after operation, of which it gives a detailed and very illuminating account. The chapter on the taking of histories is one of the best we have seen. Professor Cherry has had excellent results in the treatment by diathermy of pelvic inflammation and chronic cervicitis. In this country we have as yet had little success in this direction, and this detailed account of American methods might be of unusual value as a means of comparison and correction.

MALIGNANT DISEASE AND ITS TREATMENT BY LEAD

THE treatment of malignant disease by lead carried out with great industry and energy by Professor W BLAIR BELL and his Liverpool colleagues has excited much interest and controversy, and those who wish to review the history and the large amount of work in connexion with this subject will naturally turn to the beautifully illustrated and bulky volume entitled *Some Aspects of the Cancer Problem*,[2] edited by its moving spirit. It is dedicated to the memory of the late R D Cohen and J G Adami, Vice-Chancellor of Liverpool University, one of whose last public appearances was at the Nottingham Meeting of the British Medical Association on July 21st, 1926, when he presented Professor Blair Bell's paper on the nature of malignant neoplasia and its treatment by lead. This publication consists of a large number of reprints of articles by the numerous members of the scientific staff of the Cancer Committee and of the Liverpool Medical Research Organization, and of extracts from such papers, linked together by a running commentary by Professor Blair Bell with the object of providing a full and connected account of the work done.

In a short and modest preface, which should disarm criticism, Professor Blair Bell points out that no one can judge his own work and that the various investigations here described cover a much larger field than that of the lead treatment of malignant disease. The nature and etiology of malignant neoplasia necessarily underlie scientific treatment, and these subjects are of course discussed. About a quarter of a century ago Professor Blair Bell regarded the chorionic villi as a normally malignant tissue, the invasive power of which is arrested at a critical period, probably when sufficient nutriment has been ensured for the developing embryo by some co-ordinating factor (*hormone*) elaborated by the embryo. Analogy then suggested that some material with the power of arresting the development of, or of destroying the chorionic villi should be tried in cancer. Lead had long been known to influence growth and to cause abortion, and the later effect when investigated experimentally was found to be not necessarily due as was generally supposed to haemorrhage in the uterus, but to a selective action on the chorionic villi causing coagulation necrosis. The action of colloidal lead on animal tumours was naturally investigated, and the changes produced by intravenous injection of colloidal lead in human tumours are described with histological illustrations. The exact way in which lead deleteriously affects the cancer cell is not dogmatically stated, but it is thought to be probably both local and *constitutional*.

Special interest must attach to the important section on chemotherapy in malignant disease with particular reference to treatment with lead in which many aspects, such as the method of preparation of the lead employed, its distribution in the tissues, and its excretion in the urine are dealt with. The toxic effects of lead are considered in great detail, and special mention should be made of the interesting account of the blood change. The last part, about a fifth of the volume, contains the records of the lead treatment of patients suffering from malignant diseases many of them in a very advanced stage. Of the 227 patients treated 152 were females and 75 males, and in 10 of these the disease was completely arrested in 31 others the disease was believed to be cured and the treatment was stopped 50 died before the treatment could be completed and 106 after treatment including two deaths from acute nephritis due to lead poisoning. The results are thus most frankly set out, and the advantage of combined lead operation and *x*-ray treatment is insisted upon thus intravenous injection of lead preparations immediately after a radical operation may prevent recurrence. The lead treatment can be employed for probably all forms of malignant disease but it is admittedly difficult to some extent dangerous, and can be safely used only by those who are thoroughly experienced in this practice and have laboratory facilities at their disposal.

VERNES'S SERO-FLOCCULATION REACTION

IN a monograph on Vernes's resorcin reaction in tuberculous infection[3] Dr ROBERT LÉVY gives an account of investigations, undertaken at Nancy, into the value of the Vernes sero-flocculation reaction in tuberculosis and includes a study of the use of B C G vaccine more particularly when given subcutaneously. The book is a small paper-covered volume of 160 pages and it includes a useful bibliography. Professor JACQUES PARISOT contributes a very fair and moderately expressed preface.

Part I gives a general account of the reaction with its technique and results. A fairly full description is given of the method of carrying out the test the various apparatus needed, and the reading of the results. The test is comparatively simple to put up but reading is carried out with a highly complicated [illegible] very expensive. Results are read off on a [illegible] 0 to 15 is considered normal [illegible] or suggestive of tuberculosis (with [illegible] tuberculosis). Figures [illegible] given of the results [illegible] and in persons with act[illegible]

impression was that "if a scientist did his job and did not agitate against the State he was safe" It is perhaps not without significance that "most of the good scientific work is being done by men who 'arrived' after the Revolution," and are therefore of the right political complexion

The general impression conveyed by Mr Crowther is that there is a sense of creative effort about life under the Soviet which will unquestionably carry the country far In England he feels there is a relative "lack of the quickening spirit of creativity, there is even a lack of financial endowment," while in Soviet Russia "the proportion of the spirit of creativity to wealth is greater" He ends the book with the words "If I am right, then I do not see how in the end Soviet Russia will not become the more powerful country" We may hope that, whatever other faults our social system develops we shall never live to see the day when a university professor may have a moderately safe life at £250 a year as long as he and any enemies that he may have keep their mouths shut

NURSERY DIET

In the third edition of *The Child's Diet*[1] Dr J Sadler Curgenven repeats his earlier plea for less starch and more fat protein, and fresh food in the dietary of young children That starch in puddings and other articles of diet can be largely avoided he shows in an admirable table of recipes at the end of the book He urges that what starch is given should be in a form requiring mastication, fats may be increased in the diet by giving additional milk A brief but clear account of vitamins A B C, and D has been added, with note on the articles of diet in which they commonly occur

After reading Dr Curgenven's views one is inclined to regret that in *Nursery Cookery Book*[2] Mrs Doris B Sheridan should have included quite so many farinaceous puddings among her excellent recipes The variety of diet offered by her suggestions however solves the problem of monotonous meals, and a guarded condemnation of rice pudding should go far to relieve the gloom in many nurseries

NOTES ON BOOKS

Dr Elliot Joslin's *Diabetic Manual*[3] continues to be one of the most delightful and readable books on the subject of diabetes The fourth edition keeps fully up to the high standard of its forerunners In it the doctor will find answers to most of the questions which might perplex him or with which his patients might confront him The language and argument's are simple enough to be understood by any patient of average education and intelligence The value of this latest edition is greatly enhanced by the contributions made by some of Dr Joslin's patients The patient's own point of view is one that must help in achieving success and in prolonging life Diabetes in childhood is sometimes regarded with gloomy forebodings even with insulin at hand We recommend Joslin's illustrations and descriptions of diabetic children to parents and doctors who feel pessimistically inclined When I began treating diabetic children writes Joslin, I counted the days they lived Now I am beginning to measure their lives in decades or years No doctor who has diabetic patients in his care should omit to study Joslin's Food tables especially Table 36 giving the composition of special foods he will ponder on the credulity of the profession in recommending so many proprietary foods that contain as much starch as white bread

The *Proceedings of the Fourth Imperial Social Hygiene Congress*[4] held from July 8th to 12th 1929, present a remarkably complete survey of the world wide effort to grapple with the problem of venereal diseases These able papers and, even more, the pointed discussions to which they gave rise, should increase the general sense of the immediacy and complexity of the problem. The points stressed by those taking part in the conference were the difficulty of beginning treatment early enough and of continuing it to a complete cure the value of follow up work done by nurses and almoners the futility of controlling professional prostitutes only the danger of overlooking venereal disease among women, now decreased by treatment at maternity and welfare clinics, the failure to lower the incidence of gonorrhoea as compared with syphilis and the need for improving the social conditions of life especially by the provision of better housing

That a new edition has been called for in three years is in itself sufficient evidence of the popularity of Henderson and Gillespie's *Text Book of Psychiatry*[5] The point of view throughout is that of Adolf Meyer, in which the patient is looked upon as an organism reacting to his environment and the various mental disorders are regarded as reaction types The case reports are an admirable feature of the book but the references leave much to be desired In many places we are given only the authors names and left to imagine where the article is to be found

Dr Eicke[11] who possesses a qualification in engineering but not in medicine has written an instructive work on the organization of hospitals based on his experience of hospitals and university clinics at Frankfurt Freiburg and Heidelberg The various details of hospital administration are discussed including the admission and discharge of patients the purchase of supplies the drawing up of inventories and the working of the kitchen laundry, and system of heating as well as the arrangement of the various hospital departments a special section being devoted to hospital finance The work will be read with interest by all who are connected with the administration of hospitals

STERILIZATION OF MENTAL DEFECTIVES

MEMORANDUM BY A COMMITTEE OF THE EUGENICS SOCIETY

A CAREFULLY documented statement of the case in favour of eugenic sterilization as a measure accessory to the provision of better institutional accommodation for defectives and not as an alternative to it appears in a memorandum prepared by the Committee for Legalizing Eugenic Sterilization appointed by the Eugenic Society with Sir Bernard Mallett as its chairman and Dr C P Blacker as its secretary The committee strengthens its case by the moderation of both its claims and its proposals It neither puts forward sterilization as a panacea by which defectiveness can be eliminated from the community in a short time nor does it suggest that eugenic sterilization should be other than voluntary, making the single reservation that a defective of such low grade as to be incapable of consenting might, with the consent of his relatives, be sterilized in the unlikely event of his discharge from an institution

Statement of the Problem

The memorandum opens by stating the essentials of the problem—namely, that there are 300 000 certifiable mental defectives in England and Wales the majority of whom are the product of impaired germ cells and are liable to hand on the same defect to future generations The problem is complicated by the fact that high-grade mental *defectives and* the classes which produce them are in capable of regulating the births of their children *which* means that in future the gap between their birth rate and that of the rest of the community is likely to grow bigger and by the fact probably secondary to the former that the incidence of mental defect seem to have increased in the last twenty years and to be still increasing The committee, while approving the work of the organizations which aim at improving the lot of the defective and helping him to make the most of his limited abilities—for example the Central Association for Mental Welfare—and expressing its complete agreement with proposals for increasing institutional accommodation for existing mental defectives, states quite frankly that its own interest in

[1] Published by the Eugenics Society 20 Queen Square London W.C.1.

defective persons is chiefly concerned with limiting their propagation Society does well to make the lot of the defective as bright as possible, but it would act more wisely, and in the long run be doing the greatest kindness to defectives, by preventing them coming into existence at all The greatest weakness of proposals which aim at reducing the incidence of mental defect by a policy of wholesale sterilization is, the committee recognizes, the fact that many apparently normal persons may transmit mental defect Inevitably, therefore, the rate at which the community can be purged of its inborn defect would be comparatively slow even if defectives themselves were prevented from breeding But the question is not so much whether sterilization will abolish defect from the community, but rather whether by its means an amount of defect which might swell to unmanageable proportions will be kept within moderate limits

Inheritance of Defectiveness

Most authorities agree that mental defectiveness is inherited, though they hold divergent opinions about the method by which such inheritance takes place The views of outstanding importance are (1) that defectiveness is transmitted along Mendelian lines by a single recessive factor or by a number of different factors, (2) that it is largely produced by toxins acting upon the spermatozoon, or ovum, or early embryo, according to the law of blastophthoria The estimates of the proportion of mentally defective persons coming from neuropathic stock differ fairly widely from each other, probably, as Tredgold pointed out, owing to the different criteria adopted by investigators Tredgold himself estimates an hereditary factor in about 80 per cent of persons suffering from severe amentia Beach and Shuttleworth make a more modest estimate of 42 per cent Lidbetter, as a result of his investigations of a Poor Law area, concludes that the pauper community is comprised of two elements, one representing defect and its transmission, the other the perpetuation of low-grade stocks, not necessarily defective These two groups, he states, appear faithfully from pedigree to pedigree, revealing the distinctive characters in each group Of vital importance is the conclusion expressed by Dr E O Lewis in the report of the Mental Deficiency Committee, 1929 The incidence of low-grade deficiency was, he found, sporadic, occurring about equally in different social strata, but high-grade defectives, comprising some 75 per cent of the total of defectives, tended to spring from a subnormal and mentally retarded group, estimated as composing a tenth of the total population of the country These findings are significant in view of the fact that if it is indeed true that high-grade defectives, together with the bulk of other undesirables, tend to be born from a well-defined social group, the limits of the problem are set, and the community knows for practical purposes where are to be found the persons whose fertility is a genetic and economic menace

The committee holds that, though more information is needed about the genetic relation between defectiveness and the "*social problem group*" and about the production of defectives by the population as a whole, the known genetic facts are enough to justify society in taking all reasonable means to prevent defectives from breeding At present the relatively high fertility rate of defective persons and their lowered death rate are together operating dysgenically

The Legal Position

Having discussed the harmlessness of sterilization as carried out by vasectomy in the male and by division of the Fallopian tubes in the female—citing as an example an American series of operations for eugenic sterilization carried out on 4,517 males, with one death, and on 3,878 females, with three deaths—the committee proceeds to analyse the existing legal position in regard to sterilization whether for eugenic or other reasons Three distinct questions arise (1) Is it legal to sterilize defectives who are too defective to be able to give their consent? (2) Is voluntary eugenic sterilization legal? (3) Is voluntary therapeutic sterilization legal? Basing its conclusion largely on an opinion given by Sir Travers Humphreys in response to a specific question put by the British Medical Association[1] the committee answers the first question in the negative With regard to voluntary eugenic sterilization, the probability is that it would also be regarded as illegal, on the ground that it transgressed the law concerned with the prohibition against maiming A maim may be defined as "bodily harm whereby a man is deprived of the use of any member of his body, or of any sense which he can use in fighting, or by the loss of which he is generally and permanently weakened", and it is probable that just as castration was regarded as a serious maim because of its effect on the subject's courage, vasectomy might be held illegal on the ground that it injures the race to deprive a man of his powers of procreation On the other hand, there appears to be no doubt about the legality of voluntary therapeutic sterilization, such operations are often performed—on women, if conception would prove dangerous to health, and on men, if the operation is imperative on medical grounds

The law on the subject is obviously archaic, as unless the legal position is defined in terms of conditions prevailing to-day there is no prospect that the Board of Control would give its consent to the sterilization of defectives about to be discharged from institutional care "It is obvious to-day," states the committee, "that procreation is only a national service when the individuals procreated are capable of being socially useful When they are socially burdensome, and have to be supported out of the pockets of the useful, then procreation is a grave social disservice against which the community should be protected by suitable provisions in the law"

The Committee's Proposals

A bill, shortly to be drafted, embodying the ideas of the Committee for Legalizing Eugenic Sterilization, will consist of the three following clauses

1 A clause authorizing the medical deficiency authority or superintendent of an institution to sterilize a mental defective, subject to the consent of the parent or guardian and of the Board of Control and of the spouse if the defective is married In the case of defectives deemed capable of giving consent, sterilization will not be performed otherwise than with this consent In the case of defectives who lack the necessary intelligence to give consent, sterilization could be carried out under the safeguards above specified

2 A clause authorizing the *voluntary* sterilization of a person about to be discharged from a mental hospital for the insane as recovered provided that the further consent be obtained of the Board of Control, and of the person's parent or guardian if he be under age, or of his spouse if he be married

3 A clause legalizing voluntary sterilization, subject to appropriate safeguards, in order to prevent the transmission of hereditary defect seriously impairing physical or mental health or efficiency

The committee recognizes that the provisions of the third clause will have to be carefully safeguarded to prevent abuses by healthy persons who wish to avoid the responsibility of parenthood On the other hand, those who draft the bill will have to steer a middle course between not safeguarding enough, thereby exposing themselves to the charge of encouraging people who ought to have children to shirk the responsibility of parenthood, and of safeguarding too much, thereby incurring the reproach that they are arbitrarily, and without due cause, curtailing the liberties of responsible citizens

This memorandum deserves careful attention by all individuals and organizations concerned with the care of mentally defective persons and with the problems created in our society by their fertility It contains reasoned unpolemical statements about the inheritance of defectiveness, the fertility of the defective-producing class, and voluntary sterilization in other countries, and it analyses closely the existing means for limiting the fertility of defectives and the arguments that are brought forward against sterilization The memorandum is particularly valuable in that it shows how, in the committee's opinion, voluntary sterilization could be used as a measure complementary to segregation, how, indeed, neither sterilization nor segregation by itself can hope to offer an adequate solution of the problems arising from the inheritance of mental defect

THE ADDITIONAL BENEFIT REGULATIONS

THE Ministry of Health and the Department of Health for Scotland have now issued the Regulations[1] which are to govern the administration of the additional benefits of approved societies, and, with them, a memorandum (Circular A S 273) giving an outline of the main provisions of the new Regulations These documents are of great importance to the medical profession especially to those practising as consultants or specialists The nature and degree of this importance was indicated in three leading articles published in the *British Medical Journal* in connexion with the National Health Insurance Amendment Act, 1928, under which the Regulations are now made It will be we think, worth while for those interested, and especially for members of the Council of the British Medical Association and of its Insurance Acts and Ophthalmic Committees, to refer once more to those articles[2] At that time the Council of the Association and the Representative Body thought it desirable to resolve 'that it is essential, if the medical profession is to take part in the provision of additional treatment benefits, that these, as in the case of statutory medical benefit, shall be administered in such fashion that the services of medical practitioners who elect to give advice and treatment in connexion therewith shall not be under the control of any approved society or societies', and the Council endorsed a statement of the Insurance Acts Committee that in certain circumstances it might 'be necessary to organize those members of the profession concerned in a refusal to give service, in pursuance of the well established policy of the Association" These dangers are not completely done away with by the Regulations now issued, and they cannot, in fact, be entirely avoided except by the incorporation in the statutory medical benefit of a consultant and specialist service as recommended by the Royal Commission on National Health Insurance and suggested in the Council's Proposals for a General Medical Service for the Nation[3]

The additional benefits which may be adopted by approved societies having a disposable surplus are sixteen in number Many of them relate to an increase of cash payments in connexion with, or analogous to sickness benefit Another is dental benefit which is the subject of special regulations So far as the Regulations now issued refer to these cash benefits or dental benefits they are not of direct concern to the medical profession, though it is desirable that practitioners should have some acquaintance with them Two of the remaining benefits relate to convalescent homes and nursing services, matters in which insurance practitioners have considerable interest Another relates to the supply of medical and surgical appliances (other than dental and optical), and the remainder to such additional benefits as consultant and specialist services, in patient hospital provision ophthalmic examination and treatment and treatment at approved rheumatism and other clinics For these benefits medical practitioners are necessarily the instruments, and the conditions under which they are to be given are therefore of immediate importance to the profession An approved society may not itself provide the treatment, but it may arrange or contract with some other body (even with a body which is not easily distinguishable from a combination of approved societies) to provide it and it may contribute towards its members expenses in obtaining the treatment either through such body or from other similar bodies or from suitable private practitioners The four important considerations for the medical profession are (1) that neither directly nor indirectly shall approved societies be in a position to select particular practitioners or an arbitrarily restricted number of practitioners who shall be appointed to give treatment to the exclusion of other practitioners possessing the requisite qualifications (2) that every patient shall have free choice of the agency and as far as possible of the individual practitioner, through whom the treatment may be obtained (3) that no one must be compelled to go to a clinic if he would rather go to a private practitioner, (4) that there shall be no compulsory negotiations with any approved society or with representatives of approved societies as to the terms and conditions on which medical advice and treatment will be given

The Regulations now published do not provide that all these things shall be secured The last of them is however only a remote danger which the medical profession has it easily within its power to avoid The third may be said to be reasonably secured by the honourable undertaking of the Ministry to see that the two benefits concerned—clinic and private practitioner—are always adopted together The second is to some extent safeguarded by the Regulations but the approved societies will still be in a position to put undue pressure on their members in favour of some particular scheme or practitioner and it will depend on how the Regulations are interpreted or worked as to whether further action will have to be taken to maintain the insured person's right of free choice The first consideration is secured as far as direct action is concerned, but there is a real danger of indirect selection and control by societies and the loyalty of members of the profession and especially of hospital staffs, must be relied upon to prevent this All these matters are of urgent concern in connexion with ophthalmic benefit and the work of the National Ophthalmic Treatment Board through which it is desirable that this should be given, and the Ophthalmic Committee of the British Medical Association now has the matter under consideration

In general, the Regulations (which came into operation on July 7th) make it incumbent on the committee of management of a society that each member shall be informed of the additional benefits to which he is entitled and of the procedure he must follow when applying for and obtaining the benefit that the cost of any medical certificate required must be borne by the society, and that there should be no restriction upon the member's choice of a medium through which to obtain the benefit but that the society's contribution to the cost there and by may be the maximum entailed by the most favourable terms available under its arrangements Further the Ministry must be kept fully informed of the society's arrangements, which are subject to his sanction

INTERNATIONAL COLOUR VISION TESTS

IT cannot be denied that the question of adequate tests for colour blindness is becoming more and more important As transport develops in complexity and speed its safety and efficiency will depend more and more on signalling in colours This applies not only as in the past to railways and navigation, but to aviation and even to motor transport, for in many towns both in this country and abroad the tendency is becoming more widespread to control and guide street driving by coloured signal lights In these circumstances confusion and accidents can be avoided only by establishing a legal standard of normal colour sense, allowing no one to take charge of a motor vehicle whose colour sense falls short of this standard It is only proper, however, as the speed and efficiency of transport are rapidly making it international in character and regulation, that the standard of colour vision should be internationally agreed upon For these reasons the International Labour Office at Geneva, at the instigation of the Scandinavian Ophthalmological Congress, has conducted an inquiry into the conditions of colour vision testing in the transport services of the majority of European countries and in the United States of America and Japan, and an analysis of the information collected in this inquiry has been prepared by Professor Oblath of Trieste, whose conclusions are now available in a short and simply expressed pamphlet published in English [1]

The commonest test applied for the purpose is the Holmgren wools test, the chief advantage of which is that it affords a rapid method for examining a number of candidates Professor Oblath points out, however, that in view of the large size of the objects and the saturation of the colours a successful response to this test alone is not a sufficient criterion of fitness, moreover, although the test readily picks out red-green blindness and well marked cases of anomalous trichromatism, it misses the less evident defects of colour vision The colour lantern of Edridge Green, which has deservedly a considerable reputation, is a very complex piece of apparatus requiring a special method of working, but although it gives accurate results if used with competence and care it does not lend itself to the rapid examination of groups of candidates The most efficient and easily applied tests are those based on the use of confusion colours A valuable system of this type, of which a large number are available, is that in which use is made of the pseudo-isochromatic diagrams of Stilling as modified by Hertel (George Thieme, Leipzig, 1926) The use of these diagrams is based on the fact that persons with colour defect confuse certain colours with one another as well as certain shades, and such persons are therefore unable to pick out numerals marked in a background composed of coloured spots A second very valuable test —perhaps the most efficient of all—is that of Ishihara wherein advantage is taken of the fact that in a mosaic of colour spots the normal subject sees one numeral while the colour-blind person sees a different one, the figures being so distinct that the answer can be given without hesitation Among the test cards are diagrams designed to detect complete red-green blindness and to differentiate partial cases, thus, certain of the diagrams being made up of blue and violet spots, which appear brighter to persons with defective colour vision than to the normal subject fail to show any figure to the normal eye but do so to the dichromatic eye Other tests, as by means of Nagel's test card, and the diagrams of Schaaff, Wolffhin, Cohn, and others, are less efficient

On the whole, the conclusion must be reached that while the methods employed for testing candidates in whom a perfect colour sense is required are very numerous, all those so far suggested are in certain respects imperfect In doubtful cases the examiner, if he has to give a definite and incontrovertible decision about the fitness of the candidate, must make use of several methods before passing judgement In these circumstances it seems extremely desirable that some common denominator of agreement should be decided upon, and as a contribution to this end Professor Oblath's report deserves the most careful consideration

CRIME AND THE YOUNG CRIMINAL

IT is very difficult from the data in the Home Office compilation of statistics relating to crime, criminal proceedings, and coroners' investigations for the year 1928[1] to be sure whether crime is increasing or not Taking a short view the evidence points to an increase, for in 1928 the incidence of indictable offences per million of population in England and Wales was 3,304 5, whereas in 1927 it was 3,199 4, but on a long view, crime has diminished, for the incidence per million in 1857—the first year in which criminal proceedings were published—was no less than 4,760 5 The analysis of the different types of crime suggests that while certain offences are becoming less and less prevalent, and some are remaining stationary in their incidence, others clamour for close attention, and receive it—for example, crimes against property with violence, especially breakings-in in country districts and shop raids in towns, and certain kinds of crimes against property without violence, especially obtaining by false pretences and various kinds of fraud A grave feature of the report is the indication it gives of the relatively higher incidence of convictions for certain crimes among young persons It is too early to decide whether this is a temporary phenomenon due to war and post-war conditions, or whether it must be taken to show that many members of the younger generation, failing to find, as did their predecessors, release for antisocial impulses in drunkenness vagrancy, and so forth, are turning, and are likely to continue to turn, to crime instead Whatever may be its cause this increase of crime among the younger age groups raises very serious problems, for unless it is checked the existing relatively low incidence of crime in the mature will disappear when the present juvenile offenders pass into the older age groups The factors producing the young criminal operate in infancy and childhood, long before any question of criminal misbehaviour arises at all, and the data in the report under review offer in effect a vindication of the work of the child guidance clinics, which aim at helping the nervous and maladapted child to adjust himself to his social environment Even when the youth or child places himself within the reach of the law the modern practice is to try the effect of a warning or of probation before resorting to detention At present advantage is being taken of the Borstal institutions, but the report questions whether due use is being made of the opportunities afforded by the reformatory schools for the training and reformation of children who might otherwise follow courses which later would necessitate their committal to a Borstal institution In assessing the significance of the statistics embodied in this report Mr Arthur Locke, assistant secretary in charge of the Home Office Criminal Division, suggests that whereas the community's efforts to deal with offenders leniently and yet

[1] Home Office Criminal Statistics England and Wales 1928 Statistics relating to Crime Criminal Proceedings and Coroners' Investigations for the year 1928 Cmd 3581 H M Stationery Office 1930 4s net

with discrimination have succeeded with the older generation, there is still doubt if the same or similar methods will be effective with the generation now growing up "The natural gulf between old and young," he writes, "has been widened and deepened by the removal, during the war, of many in the prime of their lives, and also by the changed outlook caused by the very fact of the war Possibly it is worth while considering whether the younger element among the general population should not be recruited more freely for work in every field of social effort connected with the relations between the community and the offender, so that the new generation may the sooner play its due part in tackling those problems which, if they are not properly handled, will add to the troubles of that generation when it in turn grows old" We are glad to note on page lii of the introductory note that "the women of 1928 showed better in the annals of all kinds of proceedings than the women of 1911", and that "nothing has occurred in this country to suggest the same close and far-reaching connexion between criminality and the use of drugs that is suggested occasionally in the literature of some other countries"

PREVENTION OF MILK FEVER

It is well known that distension of the mammary gland either by gaseous inflation or by the injection of fluid is a specific treatment for milk fever in cattle Recently Dr J Russell Greig director of the Animal Diseases Research Institute, Moredun, Edinburgh, in a study of fifteen cases has found that this procedure brings about a rise in the blood calcium values, which occurs in direct relation to the disappearance of the symptoms He found, furthermore, in a study of eighty-two consecutive cases, that milk fever is invariably associated with a very low blood calcium content On this evidence, Dr Greig suggests that the essential cause of milk fever is acute calcium deficiency brought about by a failure of the parathyroid regulating mechanism to replace the calcium that is rapidly transferred from the blood to the milk at the onset of free lactation Assuming the truth of this concept, it follows that milk fever should be prevented by ensuring a high concentration of calcium in the blood during the first forty-eight hours after calving, when the susceptibility to attack is greatest Dr Greig in considering prophylaxis by inclusion of calcium in the diet, points out that many cows with milk fever have in fact received an abundance of calcium in their food, while, therefore it is probable that the disease may be partly controlled in this manner the calcium so administered may be lost to the animal because of a highly alkaline condition of its intestinal contents The injection of an extract of parathyroid gland, with a view to converting the deposited calcium in bone into an ionized and readily assimilable form, is found in practice to be an inadequate method of treatment The phase of increased concentration of blood calcium is transient, and liable to be followed by a phase of hypocalcaemia with definite relapse It is possible, says Dr Greig, that the simultaneous injection of a readily assimilable salt of calcium, such as the gluconate, with parathyroid extract may prove a practicable measure The method, long practised by dairymen, of allowing the udder to remain firmly distended with milk for the seventy-two hours succeeding calving, owes its success to the fact that it prevents the *sudden* transference of large quantities of calcium from the blood to the milk Unfortunately, its adoption is not uncommonly followed by a decreased milk yield More hopeful than any of the other methods discussed is the stabilization of calcium in the tissues by administering massive doses of vitamin D by the mouth Experiments conducted by Dr Greig have shown that it is difficult to produce a sustained hypercalcaemia by this method, but that by administering vitamin D for about five days before calving, the period in which the animal is most susceptible to attack may coincide with that in which the blood calcium is tending to rise It might reasonably be expected that the disease would be prevented if it were possible to maintain a high concentration of blood calcium by the repeated injection of a readily assimilable salt into the blood during the first seventy-two hours after calving As, however, the increased blood calcium concentration which follows intravenous injection is transient it has been found to be more practicable to give subcutaneous injections, which, being absorbed slowly and continuously help to maintain an increased blood calcium concentration for longer periods The critical period is passed safely in cows which have received an appropriate subcutaneous dose of calcium gluconate immediately after calving and then another after an interval of twenty-four hours

ROYAL MEDICO PSYCHOLOGICAL ASSOCIATION AT OXFORD

THE Royal Medico-Psychological Association enjoyed the hospitality of Oxford for its annual meeting during the first four days of July It is rather odd that the association, now in its ninetieth year, should not previously have visited Oxford—a progressive place from the point of view of mental treatment—since 1848 Dr T Saxty Good of Oxford was elected president, and Dr R R Leeper of Dublin vice-president The meeting had an international character, among the visitors being psychiatrists from Austria, Czechoslovakia, Denmark, Germany, Poland, and Switzerland, as well as from the British Dominions and the United States In his presidential address Dr Good traced the history and progress of Littlemore Hospital (Oxford County and City Mental Hospital) of which he is medical superintendent and in the grounds of which following the address, a reception was held He said that the hospital was opened in 1847 and even in its early days was marked by a progressive spirit The staff for example appreciated the importance of a sympathetic attitude in dealing with the insane, and also of occupation therapy During the war a group at Littlemore did a great deal of experimental work with shell-shock cases, using hypnosis and other methods In 1918 association with the Radcliffe Infirmary—a general hospital—began, and later resulted in the establishment of an out-patient clinic for nervous disorders at the infirmary Dr Good mentioned that at present the population of the mental hospital was declining while the out-patient department at the Radcliffe was expanding, this suggested that prevention was being found to be better than cure On the morning of each of the following days of the meeting papers were read and discussed Dr G A Gibson dealt with the mental changes in cardiac disease Dr F W Spielmeyer honorary professor of psychiatry at Munich, assessed the influence of circulatory changes on the central nervous system Professor Andrew Gunn commented on the use of sedatives Dr John Rickman discussed mental contact with the insane Dr D K Henderson and Miss Sarah Maclachlan reported on Alzheimer's disease and Professor C G Seligman described the relation of temperament and insanity in the Far East Professor Seligman gave an interesting interpretation of the psychology of the Japanese and Chinese and incidentally exploded the theory of [illegible] ability of the Celestial The Chinese he [illegible] their noisier and more excitable than Western [illegible] family quarrels induced [illegible] of suicides The set discussion of the [illegible] out-patient clinic which was opened by Professor [illegible] Robertson of Edinburgh [illegible] by Dr H Crichton Miller Dr William Brown Dr R D Gillespie and others At the annual dinner [illegible]

Christ Church Hall, Dr Nathan Raw, the immediate past-president, proposed the toast of "The City of Oxford," to which the mayor responded The health of "The University" was proposed by Mr Arthur Greenwood, Minister of Health, who congratulated Oxford on its accomplishment of the extremely difficult task of keeping alive the old learning without being oblivious of the new Sir Farquhar Buzzard, Regius Professor of Medicine, in responding, welcomed the Minister as a prospective health visitor, from whom, he hoped, Oxford might expect frequent visits and sympathetic after-care Dr J Greig Soutar proposed the health of "The Guests," and there were responses from Sir William Morris (whose motor works were visited during the meeting), Professor August Wimmer, professor of psychiatry at Copenhagen, and Mr L G Brock, chairman of the Board of Control Mr Brock remarked that the Board set a very high value on the work of the association He complimented Dr Good on his pioneer work in Oxford, where he had blazed a trail (in establishing association between the mental and the general hospital) which he hoped many other medical superintendents would follow The toast of "The Association" was proposed by Sir Humphry Rolleston, who also complimented Dr Good Other interesting events of an enjoyable meeting were a luncheon in New College Hall, at the invitation of the Warden and Fellows, garden parties at Newnham Park, with Viscountess Harcourt as hostess, and at Wadham College, a civic reception at the Town Hall by the mayor, and an "At Home" at Magdalen, when the Regius Professor of Medicine and Lady Buzzard received the guests

PREVENTION OF BLINDNESS

A NEW body, the International Association for the Prevention of Blindness, was formed last September, at the International Ophthalmological Congress, to study the factors, direct and indirect, which may result in blindness or impaired vision, and an English version of its first report[1] has now been issued under the auspices of the League of Red Cross Societies This lengthy document gives a very fair *summary* of a large amount of literature on the causes of blindness which has been published of recent years Much use is made of the report by the Departmental Committee on the Causes and Prevention of Blindness, appointed by Dr Addison when Minister of Health in 1920, which appeared in 1922 There are also summaries of reports from other countries It is shown that whereas there has been a considerable, indeed amazing, reduction in the communicable eye diseases in Western countries, there is a belt encircling the world in tropical and subtropical countries where eye disease and blindness take a serious toll of the economic efficiency of the peoples The heavy incidence of various forms of conjunctivitis in Egypt is an example of this, and it may be paralleled in China, Tunis, Asia Minor, and to some extent in India The report shows that much is being done to educate public opinion to the recognition that blindness can be prevented in the great majority of cases There is also evidence that where there has been a campaign of intelligent propaganda in any country the measures suggested have been welcomed by the population The report issued will form a useful document for reference, and it will be of interest to note whether this new society, born under such favourable auspices, will be able to stimulate active measures for the prevention of blindness In regard to etiology much is now known The great need is for propaganda calculated to enlighten the people themselves in the innumerable small villages scattered throughout the countries where eye disease and blindness are most prevalent A small pamphlet issued by the All-India Blind Relief Association,[1] whose patron is Sir Frederick Sykes, Governor of Bombay, deals with endeavours to improve the state of the inhabitants of the villages in the districts around Bombay The effort is small, but from the statements in this publication they would appear to be on satisfactory lines, and it is evident that the Government is taking an effective hand in the work It would be an advantage if such local reports contained a map of the district under review, and the lengthy quotations from well-known writings might be reduced, for they tend to obscure the records of the work done by the individual society

THE ORIGIN OF SYPHILIS

THE question of the time and place of the origin of syphilis has been long debated and is still unsettled Evidence of some weight has been adduced to show that the disease was imported into Spain and Portugal from the West Indies by the sailors who returned with Columbus in 1493 On the other hand, it has been urged that the description of this disease is not definite enough to enable us to be sure that it was syphilis, and that there are on record in the writings of the ancient physicians references to a disease or diseases which have been identified by some modern authorities as venereal Professor Sudhoff, after careful study of contemporary writings, came to the conclusion that syphilis must have been known in Europe before the siege of Naples in 1495 Two recent papers on this subject have lately come before us The one by Captain C S Butler and Lieutenant V Hernandez of the Medical Corps of the U S Navy[2] roundly characterizes the doctrine of the American origin as a fallacy, the other is a translation with commentary of one of the earliest papers on syphilis, that of Coradinus Gilinus (1497), by Mr Cyril C Barnard of the London School of Hygiene and Tropical Medicine[3] One of the chief difficulties in trying to come to some conclusion on this subject lies in the very vague and unsatisfactory descriptions of disease left to us by the fathers of medicine and their disciples down to comparatively recent times This difficulty seems insuperable It is as impossible to decide whether the disease which afflicted the returned sailors of Columbus was venereal as it is to identify the *ignis persicus* of Galen, under which name Gilinus classified the *morbus Gallicus*, but at least its venereal character is established by the statement "About this French disease, however, there are three things to be considered—firstly, the pustules, secondly, the pains in the joints, and thirdly, why it begins in the pudenda, such as the testicles, anus, vulva, and male organ or penis", and further, "this disease is contagious wherefore I again and again warn men on no account to lie with women who are suffering from this pernicious sickness or those who have had intercourse with men rendered dangerous thereby" The one fact which stands out most prominent in the history of venereal disease is the sudden and widespreading outbreak which occurred at and immediately after the invasion of Italy by the French in 1494-95 The authors of the American paper take a tone which suggests a feeling that to harbour a belief in the American origin of syphilis is an insult to America, and their paper consequently *smacks somewhat of advocacy*, but they and others make a very strong point indeed in urging the great

improbability of such a rapid spread from the Atlantic coast of Spain to Italy, as is postulated by the theory of American origin As they point out, there were no Spanish troops in the French Army, and those who served on the other side must have arrived in Italy too late to have caused the outbreak Besides recognizing that the disease was spread by sexual intercourse with infected persons, Gilinus (or Ghilino) distinguished it from leprosy, with which it had been confounded, and recommended the use of mercurial inunction in its cure His identification of it with the *ignis persicus* of the ancients would be of more weight did we know exactly what the last-named disease was like This pamphlet, while not the first publication on the subject, was among the earliest, as will be seen by a perusal of Mr Barnard's excellent bibliography, which gives the titles of two publications in 1495 and six in 1496 The exact date of publication of Ghilino's treatise in 1497 is unknown Much ink has been expended in the discussion of this question, and no doubt much more will still be used, and yet no incontrovertible decision will be arrived at, unless some wholly fresh evidence is discovered

SIR ARTHUR CONAN DOYLE M D

THE death of Sir Arthur Conan Doyle, on July 7th, at the age of 71 is regretted by all He was one of many writers who have started out to make a career in medicine, and then under the impulse of the creative spirit abandoned practice for the life of letters As a medical student at Edinburgh he came under the influence of a remarkable teacher, Joseph Bell, surgeon to the Royal Infirmary, whose gift of quick perception and rapid deductive reasoning from small observations he turned to good account later in delineating the character of Sherlock Holmes Bell was for ever impressing upon his pupils by example and by precept the importance of small distinctions and the *endless significance of trifles* Of Doyle he said in after years "I always regarded him as one of the best students I ever had He was exceedingly interested in anything connected with diagnosis, and he was never tired of trying to discover those little details that one looks for" After graduating M B, C M at the University of Edinburgh Doyle saw something of the world as ship surgeon in Arctic waters and on a small vessel trading to West Africa Then from 1882 to 1890 he practised obscurely at Southsea storing in his memory many scenes of medical life, both grave and gay, which he worked up afterwards into the material of fiction, in the *Stark Munro Letters* and *Round the Red Lamp* They were lean years at Southsea, he went there as a stranger, without capital or influence In the dull interludes of shabby-genteel practice he polished up his talent for writing and from time to time short stories from his pen would be accepted by editors of magazines It was in 1886, when his fortunes were at a low ebb, that Arthur Conan Doyle hit on the idea of an amateur detective who should apply the methods of Joseph Bell to the unravelling of mysteries, with a sort of medical Boswell as foil and showman *A Study in Scarlet*—the first of the Sherlock Holmes tales—was followed by a good historical novel and several romances Then on the advice of Sir Malcolm Morris he took a course in diseases of the eye at Vienna, and came to London in the hope of making a name in that specialty, but no patients knocked at the door of the house in Montagu Street, Portman Square, and the would-be ophthalmologist filled his time by writing further adventures of Sherlock Holmes for the *Strand Magazine* This was the turning point, and, apart from service during the South African war as physician to the Langman Field Hospital, he never practised again The subsequent career of this large-hearted and many-sided man is familiar to every newspaper reader

LES JOURNÉES MÉDICALES DE BELGIQUE.

THE tenth session of the well-known Belgian congress, termed "Les Journées Medicales," and organized by the *Bruxelles-Medical*, was held in Brussels at the end of June It attracted more than 20,000 visitors from forty-seven nations, including 36 Government delegates and 120 representatives of universities or scientific bodies Professor Bordet was the president and the King and Queen of the Belgians attended the opening meeting Considerable interest was aroused by a lecture by Professor J L Faure, entitled "Science et conscience en chirurgie" He emphasized the vital importance in many cases of an early operation, and remarked that even failures had their value, since they pointed the way to improvements in technique Operations were performed at various hospitals during the congress, not only by Belgian surgeons, but also by distinguished representatives from other countries, some of whom had even brought with them their assistants and *patients Besides communications on various medical* subjects, a number of practical demonstrations were arranged Special attention was paid to the entertainment of the delegates, many of whom took part in an excursion to Liege, with which the congress terminated An elaborate exhibition illustrating the application of art and science to medicine surgery, pharmacy, and public health had been prepared, and proved to be very popular Among those who were present from Great Britain were Dr Alfred Cox, Medical Secretary of the British Medical Association, and Professor G H F Nuttall from Cambridge The majority of the papers read will be published in full in coming numbers of the *Bruxelles Médical*, which, in its issue of July 6th, gives a short description of the congress

CLINICAL ADDRESSES AT WINNIPEG

IN connexion with the Annual Meeting of the British Medical Association at Winnipeg a series of special clinical addresses will be delivered at 2 p m at the Winter Club On Wednesday, August 27th, Sir William Wheeler (Dublin) will speak on "The significance of surgical recoil in visceral decompression" and Dr H C Cameron (London) will discuss Child psychology" The addresses on Thursday, August 28th, will be given by Sir Lenthal Cheatle (London) on "The primary tumour in carcinoma of the breast," and by Professor W E Dixon (Cambridge) on Drug addiction" The clinical address on Friday, August 29th, will be given by Sir E Farquhar Buzzard, who will speak on "Rest, work, and play in health and disease" The Listerian Oration by Lord Moynihan of Leeds will be delivered at the Winnipeg Winter Club on Friday, August 29th, at 9 p m

THE Metropolitan Water Board has unanimously decided to retain the services of Sir Alexander Houston D Sc, M B, Director of Water Examination after he has reached the retiring age His researches, which he will continue, have led to the solution of many problems of protection of supply sources and water purification, with advantage not only to the Board, but to the other water authorities throughout the world

THE Association of Surgeons of Great Britain and Ireland invites applications for a surgical scholarship of the value of £350, to be held for one year The object of the scholarship is to enable the holder to pursue a definite line of research or to study in specified clinics either at home or abroad Candidates in their applications are required to state the line of research or study that they intend to pursue and also to give a résumé of their past careers No testimonials should be sent, but each candidate is required to provide letters of recommendation to be forwarded under separate cover from two sponsors The election will be made in November, 1930 and applications must be forwarded by September 30th to the honorary secretary of the association Mr E C Hughes 1F, Wimpole Street, W 1.

ANNUAL TUBERCULOSIS CONFERENCE

EFFECT OF LOCAL GOVERNMENT ACT ON TREATMENT AND PREVENTION

THE sixteenth annual conference of the National Association for the Prevention of Tuberculosis was held in the Great Hall of the House of the British Medical Association, London, on July 3rd and 4th, SIR ARTHUR STANLEY and SIR ROBERT PHILIP presided over the different sessions The principal subject for discussion was the effect of the Local Government Act, 1929, on the antituberculosis campaign, and on institutional treatment and after-care The conference was largely attended by representatives of local authorities and voluntary bodies A complaint was voiced at the close that the views of the layman had not been sufficiently heard, and that the prearranged papers, mostly by professional people, had taken up an undue amount of time SIR ARTHUR STANLEY promised that this should be remembered when the programme for the next conference was framed

The Minister of Health's Inaugural Speech

MR ARTHUR GREENWOOD, M P , opening the conference, warmly congratulated the association on its educational and practical work, which had, he believed, been a large contributory factor in the decline of the disease The Local Government Act, which was to form the principal matter of deliberation, was a great step forward It conferred a larger measure of freedom and responsibility on local authorities, who would now be able to look at their various health services as a piece of co-ordinated machinery Tuberculosis work would be brought into close relation with all other local public health activities, and, indeed, he hoped, with many activities outside those of public health narrowly so called It was well, however, always to bear in mind that the Minister had considerable powers in the way of reducing State grants where services fell below normal standard, a power which he hoped it would not be necessary to use For the sake of economy, if for no other reason, he thought that all local authorities would address themselves to the problem of after-care, but beyond economy there was a larger goal of improvement in the quality of the life of the people

New Legislation and the Tuberculosis Campaign

SIR GEORGE NEWMAN addressed the conference on the effects of the Local Government Act on the tuberculosis campaign The death rate from pulmonary tuberculosis in England and Wales had fallen from 3,000 per million persons in 1847 to 700 per million last year, but still more remarkable was the decline in mortality from non-pulmonary tuberculosis, which had been halved since 1917 Factors which had brought about the decrease were social betterment and sanitary and housing improvement, special measures, such as institutional segregation, were also concerned, and credit was attributable to biological forces, such as the restriction of the field of infection (for example, the reduction of tuberculous milk, and the avoidance of personal contagion), and probably to the natural immunization of a tuberculized population The Local Government Act made possible a wiser and more effective organization of these varied means of attack and defence In all counties and county boroughs effective co-ordination was now possible The medical officer of health was adviser both to the public health and to the public assistance committee, and so could co-ordinate the two services The remedial and preventive aspects of the services were brought together under a single health authority The dispensary (as diagnosis station and general clearing house) could be conjoined with the institutions Schemes of after-care and education were now uniformly applicable to all cases of tuberculosis within the area of the authority The tuberculosis service, established some twenty years ago had no doubt restrictions and imperfections, but it had abundantly justified itself, and had proved essential in the national campaign against tuberculosis The new Act extended its opportunity of utility, as Bentham would have said, for the greatest good of the greatest number, if only the local authorities and an enlightened public opinion would use it wisely

DR J P KINLOCH, Chief Medical Officer to the Department of Health for Scotland, dealt with those aspects of the new legislation which had a special Scottish significance The vital hospital clauses of the Scottish Act, bringing the whole institutional provision for general diseases within the domain of the new health authorities, had already given impetus to the development of regional schemes of health administration which had been in course of growth for several years A new spirit of accommodation had arisen between the universities, the voluntary hospitals, and the statutory health authorities which, in the near future, would result in the pooling of experience, outlook, and service for the common good

The Effect on Institutional Treatment

DR J A WILSON, assistant medical officer of health for Glasgow, discussed the effect of the Act on institutional treatment It restored tuberculosis to the realm of general medicine, and promoted the development of an ordered scheme for its administrative control An inquiry carried out in Glasgow showed that, of 2,500 patients, 55 per cent were in an advanced stage of the disease when notified, 35 per cent in an intermediate stage, and only 10 per cent were early cases Of these patients, 64 per cent died within six months and 87 per cent within two years of coming under observation Tuberculosis, therefore, as it occurred in an industrial city, was to a large extent a hospital rather than a sanatorium disease From this survey it appeared that one bed was required for every five registered cases, and the proportion of hospital to sanatorium beds was seven to one

MR ACTON DAVIS, consulting orthopaedic surgeon to the London County Council, considered the effect of the Act on the treatment of non-pulmonary tuberculosis, and pointed out some differences in the problem as it concerned children and as it concerned adults His view was that the voluntary hospital was not the place for the treatment of tuberculosis, there was too much pressure on the beds to allow the necessary patience to be exercised, with the result that conservative treatment did not receive its full trial This was particularly the case with glandular and genito-urinary tuberculosis

The General Practitioner in the Treatment of Tuberculosis

DR G LISSANT COX, central tuberculosis officer for Lancashire, introducing this subject, said that the general practitioner should play an important part in treatment and prevention He did not do nearly as much as he might, owing to the conditions under which he worked, and his training as a student In Lancashire there was excellent co-operation, the proof being that 86 per cent of the new cases of tuberculosis were sent by general practitioners for an opinion as to diagnosis before statutory notification If the general practitioner was to do better work he must have time to examine the cases, many mistakes occurred because the time factor was inadequate Medical students, at least in England, were badly trained in the diagnosis of tuberculosis Persons suffering from tuberculosis were rarely sent to general hospitals, and the student might hardly ever see an early case A closer co-operation was required between the tuberculosis dispensaries and the general hospitals if medical men were to know the signs and symptoms

DR J COHEN, from the standpoint of a general practitioner, said it was often complained that notification was too late, but it should be remembered that patients frequently did not come to the practitioner until the disease was well advanced The dispensary was of the greatest use to the general practitioner, if it was regarded as a consultative centre, and for the sorting out of patients into categories according as they required sanatorium, hospital, or domiciliary treatment Practitioners should be invited to take an active part in the work of the dispensaries, possibly even taking turns at dispensary duty DR WILLIAM BRAND, tuberculosis officer for Camberwell, declared that the general practitioner could not stand alone in his treatment of the domiciliary patient without risk of

doing the patient an injustice, the reason being that, together with domiciliary treatment, each local authority made concurrent provision for other forms of treatment Any of these might be required in the course of the domiciliary treatment, and could be supplied through the tuberculosis officer acting on behalf of the local authority General practitioners and tuberculosis officers should by acting together be able to simplify a difficult problem

Dr B T J GLOVER, chief assistant tuberculosis officer, Liverpool, described a domiciliary treatment scheme in Liverpool in which the general practitioner was enlisted The general practitioners treating the cases rendered a quarterly report, and were paid at the rate of 3s per attendance, whether they went to see the patient or the patient to see them The chemists were remunerated for dispensing the doctors' prescriptions on the same basis as under the Insurance Act Under this arrangement the number of non-insured persons receiving domiciliary treatment by general practitioners at any time was about one thousand Dr S VERE PEARSON (Mundesley Sanatorium) desired to see more general practitioners at sanatoriums He also referred to the difficulty, in the case of patients who had had artificial pneumothorax, of getting reliable periodical refills by general practitioners after the patients' discharge from the institution Dr J G MCCUTCHEON (Glasgow) said that the great difficulty in practice was the making of early diagnosis, it would help matters if there were competent nurses visiting frequently at patients' homes to record the temperature and pulse rate, and so on Mr W TAYLOR (mayor of Deptford) was emphatically against employing the general practitioner, and in favour of the tuberculosis officer, the more of whom, he said, the better He did not want tuberculosis to fall into the hands of insurance practitioners, who could not give the necessary full attention owing to the number of patients on their lists Dr MORTLOCK-BROWN complained of the neglect of preventive aspects, and gave some instances of how the public were deprived of air, light, and space

Tuberculosis and the Young Child

The subject of tuberculosis in relation to education was introduced by Dr W L BURGESS (M O H Dundee), who gave instances of ways in which the new Act, if freely interpreted, might have a great influence on the future of education Dr GEORGE MACDONALD discussed the open-air school He had not found that attendance at a special school for tuberculous children had proved to be a handicap afterwards in obtaining employment Mrs LEAH MANNING described the open-air school at Cambridge, of which she was head mistress, and said how much it owed to the encouragement of the medical officer of health for the borough, and the county tuberculosis officer The Rachel McMillan open-air nursery school at Deptford was the subject of papers by Miss MARGARET MCMILLAN and by Dr O'CONNOR, the school's medical officer Finally, Dr GERALD LEIGHTON, of the Department of Health for Scotland, discussed the feeding of school children He deplored the insufficiency of the amount of milk consumed per head of population (one-third of a pint a day) In speaking of tubercle-free herds, he mentioned that there were many herds, in Scotland at least, ready to supply on demand raw milk guaranteed free from tuberculosis, and many more which could quickly reach that standard

The Block Grant and Tuberculosis Schemes

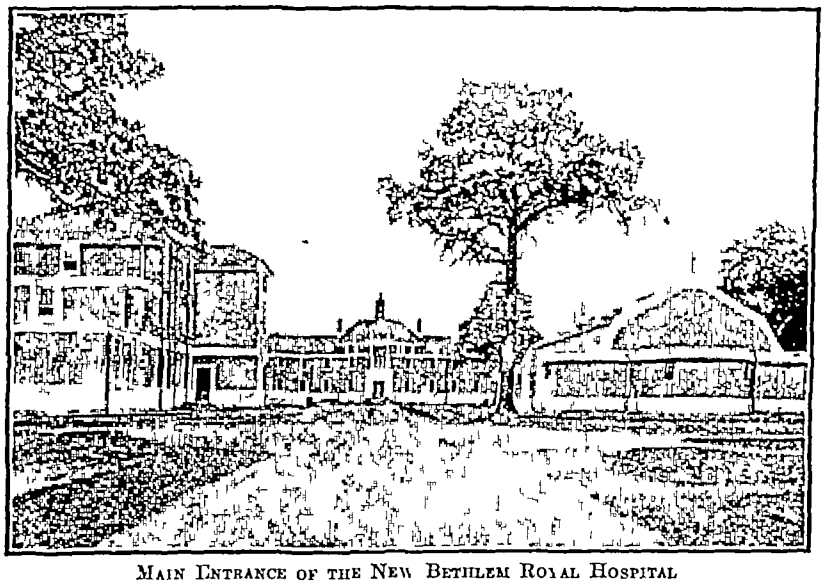
The conference was opened on the second day by Dr WALTER ELLIOT, M P, who was Parliamentary Under Secretary for Scotland in the last Government He said that it was not yet clear what the repercussions of the Local Government Act, 1919, were going to be, and it was still important that public opinion should continue to apply the steady moulding pressure by which alone permanent advances in public health or in any other sphere were brought about The underlying philosophy of the Act was that the great local authorities had now reached a stage at which it was reasonable to suppose they did not need the constant guiding and at times admonitory hand of the central authority They were advanced to a stage of equality and partnership Any system could be worked, given good will and the pressure of public opinion and the only question regarding the general aspects of the Act was whether it gave to such good will and enlightened public opinion the greatest possible scope Public health expenditure was one of the most remunerative investments a local authority could make Enlargement of the use of the public health service was more than overdue, as was also the amalgamation of the Poor Law services and the bringing into the current of public health of those pools of hospital accommodation which existed here and there in the country

Dr F E FREMANTLE, M P dealt with the effect of the change from percentage to block grant on the efficient development of tuberculosis schemes Under the old system the industrial, and to a large extent impoverished areas received the least help The new system afforded an opportunity for dealing with the problem comprehensively The block grant afforded security to the local authorities whereby they could establish their scheme over a period of years It was based on the definite principle of need The factors concerned were the size of the population, rateable value, and unemployment as measures of poverty, ratio of children to population as a measure of public health need, and, affecting rural areas, mileage The advantages of the new system were the pooling of institutions, co-operation between adjacent authorities, the possibility of providing on a large scale for complete medical and nursing services and the assistance of voluntary associations

Dr F J COUTTS, late senior medical officer, Ministry of Health, said that apprehension had been expressed lest the abolition of percentage grants should lead to serious interference with the efficiency of certain public health services This view was put forward at an early stage in a leading article in the *British Medical Journal* of December 1st, 1928 In the case of many probably most authorities the change in form of Exchequer contribution would make little difference the greater elasticity, and the freedom from the somewhat irritating central control of details of expenditure, would be welcomed The danger to be feared was the arrested development of schemes A tuberculosis service might need expansion, possibly by the provision of new dispensaries the appointment of additional tuberculosis officers or the provision of further beds for residential treatment In such cases what would be the effect of the knowledge that increased expenditure would not be accompanied by an increased grant It might be to defer desirable extensions of the scheme

Continuous Care and Social Aspects

Dr W ALLEN DALEY (London County Council) spoke optimistically of the effects of the Act on the problem of continuous care Now that the cost of out-relief came from the same pocket as supplied the money for the anti-tuberculosis scheme of the area it would no doubt be realized that it was better to subsidize an ex sanatorium patient to continue at suitable work or to train him for work than to pay him out-relief indefinitely, or to help him to pay the rent of a better house where he could keep fit than to allow him to live under conditions where he was liable to break down again Sir WILLIAM E WHYTE (Lanarkshire) described the position in Scotland



At the final session of the conference papers were forthcoming from a number of social workers on such matters as care committees, district nurses health visitors, and other health agencies Dr T W NAYLOR-BIRLOW speaking from an experience of thirty years as a medical officer of health, said that he found it difficult to ascribe the fall in the incidence of tuberculosis to what might be called direct attack, save perhaps in respect to the examination of contacts A good deal of the fall was due to the greater sobriety of the nation also to the improvement in the milk supply, and the amelioration of housing and home conditions

After the close of the conference the annual meeting of the National Association for the Prevention of Tuberculosis was held Sir ARTHUR STANLEY from the chair, submitted the annual report which was seconded by Sir ROBERT PHILIP Dr HARLEY WILLIAMS medical commissioner of the association gave a brief address on educational activities

THE NEW BETHLEM HOSPITAL.

OPENING BY HER MAJESTY THE QUEEN

THE new buildings and grounds of Bethlem Royal Hospital, at Monks Orchard, Eden Park, near Beckenham, in Kent, were opened by the Queen on Wednesday, July 9th. A distinguished assembly in a specially erected marquee awaited Her Majesty's arrival. After a welcome had been tendered by Lord Wakefield of Hythe, president of the hospital, the Queen declared the building open. A brief religious service was held, conducted by the Ven. E. N. Sharpe, Archdeacon of London, it included dedicatory prayers and the singing of the hymn, "Thou to whom the sick and dying." A memento of the occasion presented by the architects to Her Majesty consisted of an antique carved coloured ivory opium pot. On behalf of the governors, Sir William Waterlow, Lord Mayor of London, representative of the City under whose auspices Bethlem has flourished for centuries, thanked Her Majesty, and Mr. Arthur Greenwood, Minister of Health, offered to the Queen the thanks of those engaged throughout the country in the work of institutions for mental and nervous disorders for so kindly taking this opportunity of recognizing their work. Several presentations were made, after which the Queen made a tour of inspection.

MAIN ENTRANCE OF THE NEW BETHLEM ROYAL HOSPITAL
Nurses' Home on left, Administrative Block in middle, Lady Wakefield Chapel on right

For more than a hundred years Bethlem Hospital has been housed at Lambeth (or, more strictly, St. George's Fields, Southwark) in the big building under Smirke's dome. Actually that building was the third in the history of this royal foundation. The first was erected in Bishopsgate Without in the thirteenth century, originally serving as a priory and hospice, the earliest known date of its use as an asylum for the insane is 1377. The second building was in Moorfields, erected in 1676. The third was the one in St. George's Fields, opened in 1815. Six years ago the court of governors agreed that arrangements should be made for the continuance of the work of Bethlem Hospital on a larger site and amid rural amenities. The Bethlem Hospital Bill received the royal assent in 1926, and in 1928 Prince Arthur of Connaught laid the foundation stone of the new hospital in Kent. An account of the hospital in recent times and of its approaching removal appeared in the *British Medical Journal* of June 4th, 1927 (p. 1017).

The site on which the hospital buildings are placed is a beautiful park of some 200 acres, with much pleasant woodland, about ten miles from Charing Cross. In laying out the hospital the modern system of separate residential blocks for different classes of patients has been adopted, and the appearance of the buildings and their setting represents a complete emancipation from the barrack-like structures of the past.

On entering the estate the main drive leads past the house of the physician-superintendent and of the principal assistant physician, to the administration building. This building contains offices for the physician-superintendent and other members of the staff, waiting rooms for patients and their friends, the board room, and accommodation for the steward, the matron, and the head male nurse. At the rear is the Sir Edward Cooper recreation hall, built by Lady Cooper in memory of her husband, a former Lord Mayor. It accommodates 250 persons, and is equipped for all entertainment purposes.

From this point the roadway runs through clearings in the woodlands to a wide range of buildings to be known as Tyson House. This is for "restless patients," and includes sections for men and for women, accommodating eighty-four in all, with hydrotherapeutic and other treatment equipment in each section. This two-storied unit, pleasant in its immediate surroundings, is well isolated from the rest of the hospital by trees. Along another main avenue, at right angles to the principal drive, are two other two-storied blocks—Fitz-Mary House, for sixty-four women, and Gresham House, for sixty-two men. Fitz-Mary was the name of the founder of the original priory in 1247, and Gresham, of course, is a name famous in the records of old-time City philanthropy. Each of the stories in these houses is entirely self-contained, with its own dining room, day rooms, and small service kitchen, so as to separate the patients into two sections in each unit as desired by the Board of Control. Ample bed verandahs are to be provided, and the entire scheme is planned to give as much sunlight and air as possible to all rooms. A short distance away is Witley House, a convalescent unit, accommodating twenty-five men in one wing, and thirty-five women in the other, and with its own dining room, kitchen, and lounge, and recreation rooms. Here every obvious suggestion of a mental hospital has been eliminated as far as possible.

A very important block consists of the science and treatment laboratories, named after Lord Wakefield of Hythe, who has defrayed the cost of their erection and equipment. The laboratories are central to the whole design. They contain accommodation for hydrotherapy, massage, electrical, x-ray, and other physical treatments, also the central dispensary for the hospital, an operating theatre, and well-equipped research laboratories, with library and museum. The idea in designing this building has been to secure a continuance of the recognition, accorded at Lambeth, as a medical school by the University of London. It is intended to develop the Bethlem Royal Hospital as a special study centre.

Returning to the main drive, we find a very pleasant home for the nurses. It consists of three floors, giving bedroom accommodation for ninety nurses and servants, and the building, though it stands in the grounds, is amply detached from the hospital environment. In addition to the dining, recreation, and reading rooms, there are lecture and demonstration rooms. The most conspicuous of the group of buildings are the power house and associated workshops, with the kitchen and stores adjacent. Boilers are installed for the generating of high pressure steam, and the generating plant supplies electricity for general lighting and power purposes and for electrical treatment. In every respect, such as intercommunication telephones, a fire alarm system, and synchronized electric clocks, the hospital is on the most up-to-date lines. The chapel, a beautiful building, is the gift of Lady Wakefield.

In the course of some information circulated by the governors among members of the press it was suggested that any reference to the old contraction of the name of the hospital to "Bedlam" should be avoided. But, in fact, the old unfortunate associations of Bethlem, when the wards, full of misery, were a public spectacle, "the entertainment of raw minds," only give greater significance to the new Bethlem, incorporating as it does the most progressive and humane psychiatric ideas. Bethlem for many

centuries was practically the only recognized institution dealing with mental disease, and therefore it had to suffer the odium which nowadays rightly attaches to the old harsh methods prevailing in former times But to-day, in this new environment, with everything that modern psychiatric science and the new compassion for and understanding of the mentally afflicted can suggest, it is worth while to recall the past for the sake of contrast And Bethlem itself was always in advance of its time always in the front rank of mental hospitals the world over, and by its good work redounding to the honour of the City of London

Certainly at Eden Park it is still a pioneer What can be more conducive to mental recovery than the spreading grounds in which it is set, with abundant opportunities for exercise and recreation, or the residential blocks furnished after the manner of good private houses, with, by the way a single bedroom for every patient, except for some small four- or five-bed wards for special purposes, or the sunny day rooms and exercise corridors?

On the matter of finance, the annual expenses of Bethlem in the past have been met to the extent of about 75 per cent of the total from the income of the charity, and the balance from payments by friends of patients The cost of running the new hospital is difficult to forecast, but it is the hope of the governors that the additional demand they may have to make in the form of contributions for patients will be of a moderate nature and that they may be able to continue the magnificent contribution by the charity upon the same level as in the past The financing of the present enterprise has been greatly helped by the generous response, amounting to nearly £50,000 to the appeal for donations and in addition there have been the munificent gifts of Lord and Lady Wakefield, Lady Cooper, and others In the planning of what must be described as the estate, those concerned have looked thirty years ahead, to a time when it may be necessary to provide additional accommodation for patients, and they have so arranged that such expansion can take place without undue expenditure

Scotland

Resignation of Glasgow Professor

At a meeting of the University Court of Glasgow University, held on July 3rd, a letter was read from Dr Leonard Findlay, professor of medical paediatrics at Glasgow University, stating that he wished to resign his chair as from September 30th next It was agreed that the secretary of the University should be empowered to take the necessary steps to advertise for applications for the chair in order that these might be considered at the next meeting of the Court Professor Findlay, after graduating M B, Ch B at Glasgow in 1900, proceeded to the degree of M D in 1904 and that of D Sc in 1912 In 1919 he became university lecturer on the diseases of infancy and childhood, a post which had been instituted that year For a time he also acted as assistant to the professor of practice of medicine in the University In 1924 he was appointed the first holder of the Samson Gemmell chair of medical paediatrics at Glasgow University, and he has been for many years visiting physician to the Royal Hospital for Sick Children, a post which he is also resigning.

Department of Animal Genetics at Edinburgh

The new department of animal genetics of the University of Edinburgh was opened on June 30th by Sir Edward Sharpey Schafer, F R S, under the presidency of Principal Sir Thomas Holland Sir Edward Sharpey-Schafer, before declaring the buildings open, gave the address of which an abridged version appeared in last week's *British Medical Journal* (p 39) Professor F A E Crew, in presenting Sir Edward with a key to perform the opening ceremony referred to the important work of Professor Cossar Ewart, who, he said, was fortunately present that day Professor Ewart might well regard this department as his own creation and the realization of his dreams The ceremony also included the conferment of the honorary degree of LL D upon Mr Thomas Bassett Macaulay, president of the Sun Life Assurance Company of Canada, who had made a series of gifts to the department In presenting him the dean of the faculty of law mentioned that Lord Macaulay, the present recipient of the degree was descended from the Macaulays of Uig in the Island of Lewis His father had emigrated to Canada where their guest had built up one of the foremost insurance corporations in the world After the degree had been conferred Mr Macaulay said that the study of endocrinology had been one of his hobbies for at least twenty five years This might seem a strange recreation for a layman but his object had not been the acquisition of knowledge of merely theoretical value Medical science had made marvellous progress during the last two generations in combating disease, chiefly in improved sanitation and in the knowledge of the nature of infection, but he thought that most of the great problems of non-infectious degenerative diseases of the latter third of life still remained unsolved Great advances he felt reasonably certain would be made in the understanding of the endocrine glands during the next twenty five years He had been deeply interested in the splendid work that was being done in the animal genetics department of Edinburgh University, and he was pleased that the biochemical department of M Gill University, Montreal, was now actively co-operating with Edinburgh He congratulated the University of Edinburgh on the part it was taking in the great work of the future At a luncheon which followed the ceremony in the Library Hall of the Old University, Sir Thomas Holland mentioned that during the past two years Mr Macaulay had given to the genetics department of the University contributions which amounted in all to £67 000 the University he said, would endeavour to justify the confidence he had shown in its work

The new buildings of the animal breeding research department of Edinburgh University are situated at West Mains Road The original idea of this department conceived before the war, formed part of the plans of the development commissioners After the war the plans were reconsidered but shortage of money prevented development of the work on a large scale In 1920 Dr F A E Crew, who was an assistant in the zoology department of the university, was asked by Sir Edward Sharpey Schafer, then chairman of the joint committee, to take charge of the embryo department, and a few rooms in the Old Infirmary buildings were devoted to its work Here some sound scientific work was done Studies on wool began in 1923 and studies on pigs in 1927, other subjects of agricultural importance being taken up later In 1928, as the result of a gift of £30,000 from the International Education Board and of £10,000 from Lord Woolavington, the department was reorganized, and Dr Crew was appointed to the newly founded chair of animal genetics The buildings which have just been opened were then started Their purpose is to provide facilities for work of a purely scientific nature which is expected to have an important effect upon agriculture in about fifteen or twenty years' time At present inquiries are being undertaken into the inheritance of milk yield in cows, and into the ideal type of bacon-yielding pig

Edinburgh University Graduation

The summer graduation in arts and sciences was held on July 3rd in the McEwan Hall, Edinburgh Principal Sir Thomas Holland presided and conferred about five hundred ordinary degrees Along with these the honorary degree of Doctor of Laws was conferred upon Sir Thomas Barlow, Bt, Physician Extraordinary to the King Mr Max Beerbohm Sir Otto Beit, founder of the medical and scientific research fellowships which bear his family name Professor Baldwin Brown Sir Andrew Grierson, Sir William B Hardy, F R S, Director of Food Investigation, M Jean Jusserand, Dr Abbott Lawrence Lowell, Emeritus Professor Otto Schlapp, Sir David Wallace, Consulting Surgeon to the Royal Infirmary of Edinburgh, Professor W W Watts, and Dr K F Wenckebach, Emeritus Professor of Medicine, University of Vienna.

Medical Services in Fifeshire

At a meeting of the Public Health Committee of Fife County Council held on July 1st a letter was read from the Fife Branch of the British Medical Association referring to the arrangements for medical services which would fall to be made under the Local Government (Scotland) Act. The letter disclaimed any intention of even appearing to interfere with the discretion of the county council in the formulation of its schemes, but stated that there was a desire that the knowledge and experience in medical affairs which the members of the Association possessed should be placed at the disposal of the county council. It was suggested, further, that any scheme adopted by the council for carrying on the medical services of the county should meantime be regarded as of a temporary character, pending an attempt to secure unanimity and co-operation. The council's attention was further drawn to the fact that a scheme had been drafted by the British Medical Association of the lines along which it considered that the medical services of the country should be developed, and that this scheme would be made public after it had been considered by the Annual Representative Meeting of the Association this month. It was agreed by the Fife County Council to set up a subcommittee to meet a subcommittee of the Fife Branch of the British Medical Association in order to discuss this matter.

Problems of Nutrition

An address was delivered on June 26th by Dr. Chalmers Watson to the Scottish Chamber of Agriculture at Fentonbarns, East Lothian, on the subject of vitamins in relation to agriculture. Dr. Watson said that there was room for the judicious education of the farmer, the doctor, and the layman in regard to the remarkable advances that had been made in physical science during the past thirty years, and for the intelligent application of that knowledge to their work. He pointed out that after twenty years of assiduous research no vitamin had ever been isolated. There was good ground for the opinion that vitamins were specific vital forces imparted to food through the agency of the sun and other influences in the ether. The study of the interaction that took place in the soil, in the plant, and in animal tissues under their influence would prove of immense value in solving both medical and agricultural problems. Many modern foods had a deleterious effect through their having become largely devitalized at some stage of their production or manufacture, and similarly in agriculture from alterations in the vitality of the soil through excessive fertilization with artificial manures lacking in certain vital properties. He thought that chemistry was still exercising too great a role in modern agricultural and medical research. The adoption of the electron theory of matter and the knowledge gained regarding the sun as the source of all energy, had revealed the limitations of chemistry as a final guide, yet the lessons to be drawn from the work of the physicist in the past twenty years had not yet been brought adequately to bear either on agriculture or on medicine. The vital forces at work in the production of grain and root crops with maximum nutritive properties might be studied in association with the influence of irradiation in increasing the special nutritive properties of milk. Similarly many disturbances of human nutrition could be usefully studied from the same angle. A practical application of this idea was found in the increasing attention now being paid to ascertaining the degree of curative influence exerted by radium in malignant disease. He thought that the work of the skilled farmer would prove to be of an importance similar to that of the skilled doctor in the maintenance of the nation's health.

Work on Diseases of Animals

The annual distribution of prizes in the Royal (Dick) Veterinary College at Edinburgh was held on July 2nd. Sir Thomas Beare, chairman of the Board of Governors, presided, and Lord Provost T. B. Whitson presented the prizes. Sir Thomas referred to the institution of a diploma in tropical veterinary medicine, for which the classes are to open next October. He considered that this would be a most important development in giving post-graduate training to men who held appointments abroad, or who were about to take up appointments in colonial dependencies, because many difficult problems of veterinary science were to be solved there. The annual meeting of the Animal Diseases Research Association was held in the Moredun Institute, Gilmerton, Edinburgh, on the same day. It was intimated that success had been achieved by the director of the Institute and his fellow workers in their work on milk fever in cows. Its essential nature had been determined, and its identity with lambing sickness in ewes had been established. Research was also being carried out on the diseases known as louping ill and grass sickness. In regard to the latter disease, a new conception of its origin was being investigated along what was regarded as a promising line of inquiry.

The County of Lanark

A comprehensive and closely detailed account of health conditions in the county of Lanark in 1929 is supplied by the reports of Dr. J. Hume Patterson, county and district medical officer of health, and of the district sanitary inspectors. Nearly 600 pages of records and statistics give evidence of a vigilant application of the laws of social hygiene within an area of peculiar difficulty. Measures of public health, particularly in purifying the food, air, and water of the community, are carefully considered, each section being supplemented by appropriate data collected in bacteriological and chemical laboratories, hospitals, clinics, and artificial sunlight centres. Steady watch was kept on the pollution of rivers and collieries, and preventive methods were suggested in numerous instances with favourable results. A special investigation into the milk supply of the county is described, with minute analysis of the reasons for deficiency in particular cases. The results of this inquiry, which extended over a period of a year, are summarized in six tables. In addition to statistics of prevalent diseases, the survey incorporates the medical and sanitary reports of the three county districts each of which is an exhaustive record of work done during the year in every department of public health. A concluding section is contributed by the veterinary inspector, whose observations are mainly concerned with the administration of the various Acts to ensure a milk supply free from infection.

Ireland.

School Medical Inspection in Northern Ireland

At a recent meeting of the Armagh Education Committee the report was read of a subcommittee appointed to interview the Ministry of Home Affairs in regard to school medical inspection. The subcommittee conveyed the opinion of the education authority—namely, that the formulation of a scheme should be deferred pending legislation outlined in the recent report of the commission appointed to inquire into the administration of local government services in Northern Ireland. It was pointed out, however, on behalf of the Ministry, that under Part XIII of the Education Act of 1923 it was mandatory on education authorities to provide for the medical inspection of children attending public elementary schools within their area, and that the Ministry could no longer permit the county education authority to postpone action in the matter. The subcommittee stated that it was still of the opinion that it would be better to defer the formulation of a scheme until the Government had decided the nature of the forthcoming legislation in regard to medical services in Northern Ireland generally, and that the money provided for the purposes of Part VIII of the Act in the committee's approved provisional scheme could be spent to greater advantage in the provision of improved sanitary accommodation at transferred public elementary schools. In view, however, of the attitude of the Ministry, the subcommittee could not advise the education committee to postpone action under Part VIII of the Act. The subcommittee recommends the appointment of a school medical officer for a period of one year, at a salary of £600, inclusive of travelling and other expenses, and of a school nurse for a similar period.

Tuberculosis Death Rate in the Irish Free State.

At the June meeting of the Statistical and Social Inquiry Society of Ireland, Mr R C Geary M Sc, read a paper embodying a statistical study of the mortality from tuberculosis in the Irish Free State His paper is now available in pamphlet form The death rate from tuberculosis in the Saorstat in 1927 was, he said, the ninth worst in a list of twenty-four countries After reaching a high peak in the early part of the present century it began to fall, the decline had ceased during the years of the European war, but recommenced in 1919, though more slowly Mr Geary calls attention to the fact that in the Free State the mortality due to tuberculosis is at its highest in young adults, a feature which contrasts with the position in other countries, including England and Wales, Scotland, France, and the United States Two distinct types of pulmonary tuberculosis appear to exist according to whether the patients dwell in country or urban areas An analysis of the rates in the various Irish counties during the past few years would seem to indicate that in the eastern zone the rates are high, in the northern and southern zones they are medium while in the midland and western zones the rates are low The ravages of tuberculosis are worse in Wexford than in any other county of the Free State, and evidence is adduced suggesting that the marl areas in that county are an important factor in the local prevalence of the disease In Dublin city and in the surrounding urban districts a close correlation was traceable between housing conditions and tuberculosis, but in other towns this is less marked Though the decline in the mortality has been manifest in the various social classes, there is said to be a great disparity between the mortality rates in the richest and poorest sections of the population Mr Geary recommends the institution of an exhaustive inquiry into occupational mortality covering the whole of the Free State, this inquiry, he remarks, should extend over a sufficient period of years in order to obtain significant results

Lunacy Certification.

Last week, before Mr Justice Sullivan, an action was heard in which Patrick Moore of Clonee, co Meath, claimed damages against Dr Michael S Walsh of North Frederick Street Dublin, for alleged negligence in issuing a certificate on May 6th, 1927, to Mr Charles Kenny, District Justice, at the Dublin district court, certifying that the plaintiff was a dangerous lunatic The defendant denied that there was any negligence in the issuing of the certificate or that the plaintiff had suffered any injury The plaintiff, in evidence, stated that he had been examined by Dr Walsh, when, as he alleged, he was falsely charged in the Dublin district court with attempting to commit suicide at Dun Laoghaire Harbour on May 5th, 1927 In consequence, he said, he had been confined in Grangegorman Mental Home until June, 1927, and was transferred later to Hampstead Mental Home by order of the Chief Justice and placed under the care of Dr Eustace He was afterwards transferred to Carlow Mental Home by direction of the Chief Justice On cross-examination he declared that he had heard wireless messages warning him that he was being pursued by assassins He had no wireless set, but he could still hear messages, and he had driven his car to co Lough to escape He had gone to Dun Laoghaire to seek the protection of a British man-of-war He admitted having been convicted at Trim Circuit Court of drawing a loaded revolver upon Martin Dwyer in 1924 In support of his case the plaintiff called Dr Donelan and Dr Eustace, both of whom stated that at the time of his detention in their homes he was suffering from delusional insanity Dr Walsh, examined by Mr M Maguire, K C, said that he was requested by the district justice to examine the plaintiff, and did so in a private room at the district court on May 6th, 1927 He had the charge sheet before him, stating that the plaintiff had attempted to commit suicide at Dun Laoghaire on May 5th He made a thorough examination of the plaintiff, and asked him a number of questions As a result he was satisfied that the plaintiff, as he had certified was suffering from delusional insanity The jury, without leaving the box returned a verdict that there was no negligence on the part of the defendant, and judgement was entered for Dr Walsh accordingly

Complaint Against a Dispensary Doctor

At a recent meeting of the County Wexford Board of Health a letter was read from the secretary of Local Government and Public Health stating that he had received the report of Dr Sterling Berry, medical inspector on the sworn inquiry held by him into a complaint by *William Staunton, Ballybrack, Foulksmills*, as to the attendance of Dr P W O'Connor, Carrigbyrne Dispensary district, on Mrs Staunton After dealing with the evidence, the letter stated

> A misunderstanding appears to have arisen on this occasion, and it is possible that Dr O Connor was not aware that the messenger was sent specially to request his attendance at the patient's house Dr O Connor described Mrs Staunton's condition as chronic and stated that he told her on January 26th that her only chance was to go into hospital He had attended her several times at the dispensary and at her house twice during the twelve months previous to her death Having regard to the nature of Mrs Staunton's illness chronic Bright's disease and to the misunderstanding referred to the Minister does not consider that any action on his part is called for '

Correspondence.

"DISEASE" OR "TISSUE REACTION"?

SIR,—Dr Kinnier Wilson, in his first Morison Lecture, published in your issue of July 5th, has done medicine a service in reminding us of the general laxity of thought and speech among medical men when they speak of diseases and pathological lesions, and relate symptoms to morbid anatomy With his main argument I am quite in agreement At the same time the presentation of a subject in a strictly philosophical manner raises certain difficulties which are avoided by the use of conventional phraseology We therefore speak of "lesions" rather than of "reactions," of "diseases" rather than of "clinico-pathological syndromes", and in relating symptoms to localized lesions side track the train of thought which is necessary when we attempt to visualize their exact relationship to one another The pathogenesis of symptoms is a subject which has received much attention of recent years, and the neurologist has not lagged behind the cardiologist and the gastro-intestinal specialist in this fundamental part of medical thought But when he finds himself in so vast a *terra incognita* as the cerebrum he may be excused if he falls back on conventional phraseology, and speaks of a lesion in a certain situation "causing" a certain group of symptoms

As an example of this laxity of language and, as he appears to consider, of thought, Dr Wilson has quoted a phrase from an article which I recently published on acute disseminated encephalomyelitis following influenza Taken out of its context it would appear that I have, in Dr Wilson's words, erected "a mere tissue reaction [perivascular demyelination] into a disease" I was however at some pains to show in this and other articles on the same subject, not only that the clinical aspects of various cases of the "disease" agreed as closely as did their pathological lesions, but also that these lesions differed in certain important respects from those of other diseases in which perivascular demyelination was a prominent and characteristic feature I do not accept his dictum that before we use the term 'disease" we must know the etiology of the condition On that basis carcinoma is only a tissue reaction, which as we know may be brought on by at least two irritants, tar and x rays But until we understand its etiology better we are probably justified in thinking of it as a "disease" rather than as a stage of inflammation.

My thesis was that the clinical and pathological picture named "acute disseminated encephalomyelitis" was one

and the same whether it came on after small-pox, vaccination, measles or influenza, and that it was not merely a part of those "diseases" In this sense it is a "disease *per se*," just as *acute miliary tuberculosis is a disease per se* whether it comes on after measles, whooping-cough, or influenza We now know that acute miliary tuberculosis is only one among many forms of disease caused by the tubercle bacillus, but as at present we have no knowledge of the etiological agent of acute disseminated encephalomyelitis or of the other demyelinating diseases of the nervous system, we cannot do more than collect them into a group, and form subgroups for such well-defined conditions as disseminated sclerosis and Schilder's encephalitis, which for the moment we dignify with the title of "diseases"

It seems to me that this method, far from confusing our thoughts, clarifies them No doubt it can be carried too *far, but I may remind Dr Wilson that it formed the* basis of our knowledge of all the infectious exanthemata, and still forms the basis of our diagnosis and prophylaxis in many of these "diseases"—I am, etc,

J G GREENFIELD

Pathological Laboratory National Hospital, *Queen Square, W C, July 8th*

TREATMENT OF EYE DISEASE BY TUBERCULIN

SIR,—In the evening of my life it is refreshing to read a kindly recognition of my life's work by Dr Stobie (June 28th, p 1195), who speaks as the official head of the tuberculosis department in one of the chief centres of learning in the Empire May I at once set at rest his anxiety about my views upon the character of a positive test with tuberculin? In every case the *focal reaction* must play a dominant part in the diagnosis of active tuberculosis What is a focal reaction? *It means more* than a definite, sudden inflammatory response, perifocal in its nature and range, because it produces after-effects—diminution of redness, mitigation of pain, lessened swelling (tension), lessened exudate, and subsequent betterment of function—which imply not merely the nature of the cause, *but (of greater importance still) successful treatment*

Entering upon a new field of inquiry, in which I had no help from previous workers, I was prudent enough to use extra care to avoid severe focal reactions in such a small and delicate organ as the eye Perhaps I paid too much respect to the prevalent notion that a severe focal reaction might impair vision, or might be dangerous by causing generalization For more than ten years I have been using tuberculin in the diagnosis and treatment of tuberculous conditions of the eye in isolated cases, but I was specially careful not to produce a severe focal reaction In my early cases with eye specialists a single severe "flare up" in cases of iritis or iridocyclitis or retinitis might have been the doom of my investigations in search of truth Therefore, in these early cases, I used the intracutaneous method for the first test in order to determine the degree of allergy in each case, and thus I was able to avoid severe focal reactions by choosing further test doses according to the title of immunity In the few cases reported, which are merely an advance guard, anyone reading between the lines will recognize evidence of a focal reaction

If Dr Stobie would come once to the tuberculin dispensary, where practically all this work was carried on, he would see in the [illegible] that the focal reactions occur [illegible] exerted in each case Quite apart from [illegible] thought that the work [illegible], a focal reaction in the [illegible] be of an importance [illegible] sorption of inflammatory [illegible] once but [illegible] the maintenance of [illegible] reaction [illegible] any time [illegible] specially [illegible] severe inflammatory disturbance [illegible] form of disappearance of pain [illegible] products and improved vision is [illegible] my diagnostician or physician could desire [illegible] hitherto to the disease had been slowly [illegible] in spite of all the physicians [illegible] Stobie will see from [illegible] various other records [illegible] either [illegible] his [illegible]

Diseases of Animals

[illegible] prizes in the Royal Dover, [illegible] was held on July , and [illegible] the Board of Governe not [illegible] Whitson presented deed, [illegible] stitution of a duty "in [illegible] classes eye [illegible] and can do good" I have not been over-hasty in publishing an interim report on cases which I have watched for three years

After many years' experience I have submitted definite results so that I may obtain further material for observation and study I would seriously invite Dr Stobie to take up this work with eye specialists at the ophthalmological department, Oxford He will be abundantly repaid, if he will start afresh on new lines He will soon give up his non-specific antigen, which is a contradiction of terms, but he must not expect tuberculin to be "rapid in action", "slow and sure" are the ways of tuberculin There is not space or time to discuss the idea of "shock tactics" in tuberculin treatment In my judgement "shock" plays no part in tuberculin treatment unless by accident an *intravenous* injection has been given instead of a subcutaneous—I am, etc

London, W July 6th W CYRIL WILKINSON

PERSISTENT FOETAL BLOOD SINUSES

SIR,—I was much interested to read in the *British Medical Journal* for June 28th (p 1173) of Mr E Watson-Williams's *encounter with the petro-squamous sinus* Little more than a year ago, when curetting the Eustachian tube in the course of the radical mastoid operation, I accidentally fractured a rather thinned-out roof of the tube, and opened into a still persisting foetal sinus—the accessory blood sinus of Kelch The case had a rapid fatal termination, from a secondary cavernous sinus thrombosis, the organism isolated at the post-mortem examination from the thrombosed sinus being the *Staphylococcus aureus* This striking case led me to publish a paper called "The persistence of foetal blood sinuses and their relation to the middle-ear spaces" in the *Archives of Otolaryngology*, September, 1929

Apparently, when infection of these sinuses takes place, the result is often fatal Vermeuve reported three fatal cases of septic thrombosis of the petro-squamosal sinus in the *Revue de Laryngologie* in 1921 My own view is that these foetal sinuses are often present in the fully developed temporal bone, and that they play a very important part in *transmitting infection from the middle-ear cavities to* the interior of the skull—I am, etc,

J P STEWART, M D, F R C S Ed

Edinburgh, June 28th.

THE OCCIPITO-POSTERIOR CASE

SIR,—I have read with interest Dr A H D Smith's letter in the *British Medical Journal* of June 28th (p 1185), in which he mentions three cases of face presentation occurring with manual rotation of occipito-posterior presentations, and subsequent application of forceps He states that he can find no reference to the occurrence in the literature Permit me to make a suggestion which may be of use by way of explanation

In some textbooks casual reference is made to the secondary development of a face presentation in cases where a primary occipito-posterior existed During my assistant mastership at the Rotunda Hospital I can recall some half-dozen cases of face deliveries in which *primary occipito-posterior positions existed, without,* however, any manipulation having produced the change from occipito-posterior to face In Tweedy's *Practice of Obstetrics*, under the diagnosis of occipito-posterior presentations per vaginam, it is stated that the concavity of the sacrum even at a late stage in labour is found relatively empty, so that the examining finger can be pressed well into this region of the pelvis In two of Dr Smith's cases this possibility may have some relation to the eventual production of a face presentation

At the period when manual rotation is usually attempted—that is, when, as Dr Smith says, the os is fully dilated—*the forehead of the foetus is impinging against* the upper and back part of the pubes, whilst the nape of the foetal neck is in contact with the promontory As each succeeding uterine contraction occurs contact of the forehead against the pubes increases flexion, and advance continues to be slow until release of the *forehead takes* place, and with it a sudden and partial extension of the

head, so that the occiput suddenly fills the hitherto empty sacral concavity

The actual mode of delivery will depend on the integrity of the pelvic floor and the size of the pelvis

1 If the pelvic floor is intact reflexion will occur and delivery follow as R O A or L O A

2. If the pelvis is small or the foetus unduly large or if the uterus tires the posterior position will persist, or at best become one of deep transverse arrest

3 If the pelvic floor is damaged the posterior position will likewise persist but the configuration of the head immediately after delivery will be normal

4 If the momentary extension which I have said is necessary to bring the head through the brim is maintained (multipara) the second mechanism of delivery of occipito-posterior is prone to occur—that is in which the glabella hitches under the pubic arch and delivery is as a brow

5 If the foetus is below average size and the pelvis either average or roomy the extension referred to may become complete, and a mento anterior face presentation result

May I suggest that in performing the manual rotation the writer released the forehead from behind the pubes thereby allowing the occiput to make full use of the empty sacrum, and with the application of forceps rendered the extension of the head complete

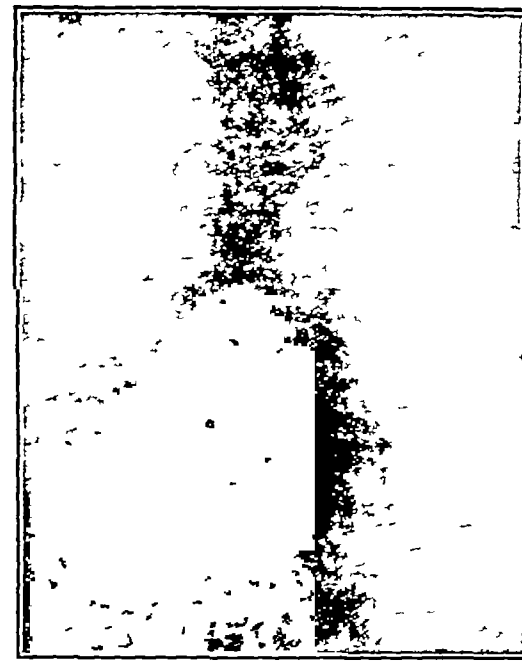
I cannot speak with any experience of manual rotation, having never found it necessary or advisable I am fully aware of its efficacy in the case of a multipara with relaxed soft parts but I have always been at a loss to understand the obstetrics of performing a movement of the foetal head in a manner altogether contrary to that by which Nature effects it Rotation only begins with the initial contact of the head with the pelvic floor, and is completed when the head is so far through the vulva that spontaneous delivery can be effected by expression of the chin

May I in conclusion, suggest that a number of the successful results claimed to-day for manual rotation in occipito-posterior cases are due to the simple stimulation of the maternal passages with the hand (and this in primigravidæ must be considerable) while Nature completes the manœuvre in her own time, and in her own immaculate way —I am, etc,

WENTWORTH TAYLOR, M D, F R C S I

Cardiff June 30th.

AORTIC ANEURYSM SIMULATING BRONCHITIS



SIR,—On page 1048 of your issue of June 7th Dr L G Hill reported a case of aortic aneurysm simulating bronchial asthma which moved Dr F William Cock (June 14th p 1118) to comment upon a similar case of which he had unearthed the record In each of these instances the condition was first demonstrated at the necropsy and a period of no less than eighty-four years separates the two, so I feel justified in bringing to your notice the following case which has just come under mine

A gardener aged 50 otherwise apparently a healthy subject consulted his medical adviser early in April 1930 on account of cough and rawness of the chest of about two weeks duration On treatment the rawness was relieved but the cough accompanied by the production of a fair quantity of tough phlegm, did not entirely disappear and towards the end of the month he began to observe some shortness of breath he did not, however find it necessary to discontinue his normal work

On June 11th, at 11 p m. Dr S S Nicholson was called to see the patient and found him in a state of acute respiratory collapse with marked dyspnœa and cyanosis a pulse rate of over 120 and a subnormal temperature Adrenaline and morphine having been administered hypodermically the patient was removed to Worthing Hospital where he was placed under the care of Dr Bernard Haigh On the passing of the initial acute attack the patient assumed the appearance of a case of advanced asthma with typical exacerbation separated by periods of partial relief Orthopnœa was pronounced respiratory spasm was high inspiratory and expiratory and cough was irritating and productive of tenacious sputum

Adrenaline and morphine continued to be given at nights and an expectorant potassium iodide mixture with occasional hominis aspirated the cough and soothed the chest but on June 14th the temperature commenced to swing between 99 and 101° F On the two following days the swing continued the temperature going as high as 103° F and a dull patch was recognized at the base of the right lung where the air entry became affected, for which reason I was asked, on June 16th, to report on the chest condition from a radiological point of view

A radiopaque zone was evident at the right base but the patient's condition precluded anything but the most rapid examination, and I was unable to say more than that it appeared to be due to blockage of a basal bronchus or pulmonary to bronchiectasis On the other hand I was able to demonstrate very definitely the presence of a large aneurysm of the first part of the arch of the aorta of which I enclose a reproduction of one view The oblique view which had to be taken with the film at some distance from the patient is probably not suitable for reproduction in reduced form but I hope to

have the opportunity later of making a more exhaustive examination as there is a suggestion in that view of vertebral erosion A history has been elicited of an attack six years ago of precordial pain of a stabbing character shooting towards the right and sometimes to the back this attack followed a strain sustained while at work and apparently settled down sufficiently to be classed as neuritis

There is a popular saying of the origin and exact wording of which I am not cognizant, that events of an unusual nature are apt to occur in threes, I do not put this forward as the actual third case, but I think it worth recording to complete the present triad It would appear that either the condition is sufficiently rare to warrant its publication, or, alternatively, it is less uncommon than is usually suspected for this case despite the radiological evidence, is still clinically one of bronchial asthma with an added lesion at the right base the physical signs of the aneurysm being masked by those of the lung condition while the remote evidences refuse to manifest themselves in convincing fashion

I am indebted to Drs Haigh and Nicholson for permission to publish this early account of the case while particulars of those in your issue of June 7th and 14th are still fresh in the mind of readers who may be able or disposed to advance further view on the subject —I am, etc

R BOULTON MYLES

Worthing June 23rd

TREATMENT OF PRURITUS ANI AND ANAL FISSURE AND SPASM

SIR —Dr Howitt's interesting article (June 28th, p 1163) illustrates the old saying that there are more ways of killing a dog than by hanging I have no doubt that cases of anal fissure and consequent spasm resulting from operations on haemorrhoids can be relieved by dial ether administered in the way Dr Howitt describes Personally the method sounds unpleasant from the patient's point of view,

Applications should reach the War Office not later than July 20th All information as to conditions of service and emoluments may be obtained from the Under Secretary of State, the War Office (A M D 1), Whitehall, London, S W 1

Surgeon Captain F S Dudley, R N , has been appointed to succeed Surgeon Captain J S Dudding, R N , as Director of Medical Studies and Professor of Hygiene at the Medical School, R N College, Greenwich

DEATHS IN THE SERVICES

Surgeon Charles James Seddon Kelsall, R N (ret), died at Hove on June 12th He was educated at King's College Hospital, took the M R C S and L R C P Lond in 1886, and, after filling the post of house surgeon at King's College Hospital, entered the Navy as surgeon on February 21st, 1889, but retired after a few years' service

Lieut Colonel Ernest Reinhold Rost, O B E , Madras Medical Service (ret), died at Putney on June 23rd, aged 57 He was born at Ealing on August 22nd, 1872, the son of Dr Reinhold Rost, the famous Pali scholar and librarian to the India Office, and was educated at Highgate School and at St Mary's After taking the M R C S and L R C P Lond in 1895, he entered the I M S as surgeon lieutenant on January 29th, 1896, became lieutenant colonel on July 29th, 1915, was placed on the selected list for promotion on August 23rd, 1919, and retired on September 3rd, 1922 Most of his service was spent in civil employ in Burma, where he became civil surgeon, Rangoon, and took a large part in the foundation of the Rangoon Medical School, of which he was superintendent, as well as lecturer in surgery During the war of 1914–19 he served in East Africa, and on the North West Frontier of India during the Afghan war of 1919 After his retirement he practised in Putney, and also worked as specialist in tropical diseases under the Ministry of Pensions His special subject was leprosy, on which disease he had conducted important investigations He received the Kaisar i Hind medal, first class, on January 1st, 1913, and the O B E on June 3rd, 1918 During his service in Burma he became a convert to the Buddhist faith, and after his retirement took a prominent part in the work and propaganda of the British Buddhist Society

Obituary.

ANDREW RUTHERFORD, M B , B Sc , F R C P Ed ,

Assistant Physician to the Royal Infirmary, Edinburgh

THE death took place with startling suddenness at his residence in Palmerston Place, Edinburgh, on July 4th, of Dr A Rutherford He had carried out his ordinary duties on the day prior to his death, which was completely unexpected

Andrew Rutherford was a native of Hawick, where he was born in 1890, and a nephew of the late Professor William Rutherford of Edinburgh University After graduating M B , Ch B at Edinburgh in 1912, he acted as resident physician in Chalmers's Hospital, Edinburgh, and later for a year as an assistant in general practice in his native town, afterwards taking up the study of public health and graduating B Sc (Public Health) in 1915 For many years he acted as medical officer of health to the burgh of Hawick, and took a great deal of interest in the general problems of preventive medicine Joining the Royal College of Physicians as a member in 1921, he proceeded to the Fellowship in 1924, and shortly thereafter was elected an assistant physician to the Royal Infirmary of Edinburgh

Dr Rutherford held various posts in connexion with the Edinburgh Medical School, being for a time pathologist to Chalmers's Hospital and Deaconess Hospital, as well as assistant pathologist to the Royal Infirmary and assistant in the University department of pathology For several years before his death he conducted an extra-academical class in pathology, to which he always managed to attract students in large numbers During the war he held a commission in the R A M C from 1915 to 1919, seeing service especially in the East Among the work performed by him in this connexion was the organization of laboratory and research work in two large hospital bases Here he wrote two reports for the Government of India, one of which embodied an important investigation of epidemic jaundice in the North-West Frontier Field Force during 1917 Numerous contributions to current medical literature issued from his pen, especially after his return from the war, one of which, entitled "Fifteen cases of liver atrophy," was published in the *British Medical Journal* in 1920, and afterwards expanded in the *Quarterly Journal of Medicine* in 1923 He was joint author of an article on cardiac ball thrombus, which appeared in the *Lancet* in 1920, and also wrote on lupus erythematosus in the *British Journal of Dermatology and Syphilis* in 1920, on food poisoning and preservatives, and on the treatment of dysentery

Dr Rutherford was one of the most successful of the younger teachers in the Edinburgh Medical School in clinical medicine and in pathology In an epoch when the knowledge of younger physicians is too apt to be derived mainly from laboratory practice, Dr Rutherford's sage experience, drawn from the study of clinical and preventive medicine, was highly valued by his colleagues His wide scientific attainments, together with his kindly and sympathetic disposition, had gained for him a high place in the estimation of his medical confreres, students, and patients His death is not only a severe blow to his immediate circle of friends, but will be also a great loss to the Edinburgh Medical School

Many readers will learn with regret of the death of Dr JAMES METCALFE, on July 1st, after a long illness, which caused his retirement from active practice two years ago He was born in December, 1863, at Tongue, in Sutherlandshire, and studied medicine at the University of Edinburgh After taking the L R C P and L R C S Ed diplomas in 1886 he went to Bradford as resident medical officer of the Royal Infirmary, and afterwards settled there in general practice In 1896 he graduated M D with honours at the University of Brussels For some years he held the appointment of honorary surgeon to St Catherine's Home for Cancer and Incurables at Bradford At that time he took a very active part in the work of the British Medical Association He was a member of the Central Council from 1911 to 1913, and spoke in many of the debates on national insurance at the Representative Meetings held during those troublous times When the Association held its Annual Meeting at Newcastle in 1921 he acted as joint honorary secretary of the Section of Radiology and Electro-therapeutics This was a subject to which he had applied himself more and more when in practice at Bradford, and shortly before the war he migrated to London, setting up practice as a consulting radiologist in Harley Street For a time he was medical officer in charge of the x-ray department of the German Hospital at Dalston, and was later appointed physician in charge of the x-ray and electrical departments of the Prince of Wales's Hospital, Tottenham, and lecturer at the North-East London Post-Graduate College During the war he served on the staff of the Edmonton Military Hospital, and afterwards held the post of radiologist to the North Middlesex Hospital Dr Metcalfe published a number of papers on x-ray diagnosis and treatment, and had been an active member of the Roentgen Society and of the Electro-Therapeutic Section of the Royal Society of Medicine, he was also a Fellow of the American Electro-Therapeutic Association

News has been received from South Rhodesia of the sudden death, at the age of 52, of Dr FRANCIS HEYGATE ELLIS, senior Government medical officer at Bulawayo and medical superintendent of the Bulawayo Hospital and Asylum He received his medical education at St Bartholomew's Hospital, obtaining the M R C S and L R C P diplomas in 1902, after which he served in turn as house surgeon to the Seamen's Hospital, Greenwich, and house-physician, registrar, and pathologist to the City of London Hospital for Diseases of the Chest He went to Rhodesia in the autumn of 1905 as medical officer in the British South African Police In 1906 he was made director of the Pasteur Institute, Salisbury, and two

years later was transferred to the medical director's department as additional health officer After a period of service as acting assistant medical director and district surgeon at Bulawayo he was promoted medical inspector and chief compound inspector at Salisbury Dr Ellis's war service revealed the same strong sense of duty that characterized his work as Government medical officer During the East African campaign he was several times mentioned in despatches for gallantry and distinguished conduct and was awarded the Military Cross In 1917 he accompanied the 2nd Rhodesia Regiment overseas, he was given a commission in the R A M C and reached the rank of major, serving until 1919 in France After the war he resumed his post at Salisbury and in 1925 was appointed senior Government medical officer at Bulawayo, where he threw himself heart and soul into the work of the memorial hospital lately taken over by the Government In the British Medical Association Dr Ellis had been honorary secretary of the Mashonaland Division and of the Rhodesian Branch, and from 1926 to 1929, was chairman of the Matabeleland Division Last year he was appointed a member of the Rhodesia Medical Council He leaves a widow and three children

UNIVERSITY OF LONDON

Dr L J Witts has been recognized as a teacher of medicine at Guy's Hospital Medical School, and Mr G D Robertson as a teacher in laryngology at St Mary's Hospital Medical School

The new premises of the University Union in Torrington Square were opened by the Chancellor Earl Beauchamp, on June 12th

Applications are invited for the William Julius Mickle Fellowship of the value of at least £200 It is awarded annually to the man or woman being resident in London and a graduate of the University has in the opinion of the Senate done most to advance medical art or science within the preceding five years and has therein shown conspicuous merit Full particulars can be obtained from the Academic Registrar

A Paul Phillip Reitlinger prize of £30 will be awarded on December 3rd 1930 provided there be a candidate of sufficient merit It is granted for the best essay embodying the result of some research work on a medical subject carried out by the candidate Regulations for the award of the prize can be obtained from the Academic Registrar

It has been arranged to pay to Miss Kathleen E Chevasseut, M Sc £25 *in respect of 1929 out of the Thomas Smyth Hughes* Medical Research Fund

Diploma in Psychological Medicine

Regulation 4, Part B (ii) for the diploma in psychological medicine is to be amended to read as follows

(ii) Psychological Medicine (two papers and a clinical and oral examination) In order that candidates may have the option of showing either (*a*) a higher knowledge of mental diseases (psychiatry) and a less advanced knowledge of mental deficiency or (*b*) a higher knowledge of mental deficiency and a less advanced knowledge of mental diseases (psychiatry) Paper I will be a general paper to test the candidate's knowledge of both mental diseases (psychiatry) and mental deficiency and Paper II will be special and will consist of two separate alternative sections, the first section relating to mental diseases (psychiatry) and the second section to mental deficiency The oral and clinical examination will be designed to test (as in Paper I) the candidate's knowledge of both psychiatry and mental deficiency Candidates will be permitted to take only one of the two sections of Paper II at one and the same examination and each candidate must state at the time of entry which of the two sections he will take

University College Hospital Medical School

The annual report of the Graham Legacy Committee for 1929–30 records that the activities of the laboratories continue along the usual line Grants amounting to £160 were made to the following six workers who have been engaged in inquiries (1) Dr C Bolt on gastric secretion (2) Professor W E Boycott breeding experiments with Limnaea (3) *Dr G R Cameron experimental calcification* (4) Dr A G Levy the effect of ultra violet light on sensitized animals (5) Dr J W McNee the metabolism of bile especially in relation to the spleen (6) Dr F H Teale immunity *in vivo* and *in vitro*

Dr G R Cameron continues to hold the Graham scholarship Professor Boycott has been reappointed Director of Research under the Charles Graham Research Scheme for one year from September 1st 1930

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION TO THE COUNCIL

ON July 3rd three Fellows, retiring in rotation, were re elected to the Council for the full period of eight years The election was uncontested, and the result of the poll was as follows

	Votes	Plumpers
Sir PERCY SARGENT	521	43
VICTOR BONNEY	514	52
ROBERT PUGH ROWLANDS	497	33

In all 629 Fellows voted, including 110 Fellows resident out of the United Kingdom, in addition, 8 votes were found to be invalid

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

THE following candidates, having passed the final examination of the Irish Conjoint Scheme have been admitted Licentiates in Medicine and Midwifery L H C Earl, J A Finegan, J McCurdy

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons has this week passed the Housing (No 2) Bill through the report stage and third reading, and has considered in committee new clauses proposed to be added to the Finance Bill. A standing committee has examined and amended the Workmen's Compensation (Silicosis) Bill The Lords' amendments to the Coal Mines Bill were also down for reconsideration by the House of Commons

Rheumatism Clinics

On July 2nd Mr Greenwood received a deputation from the Parliamentary Medical Committee, which argued in favour of a central advisory committee to guide and correlate the work of rheumatism clinics throughout the country Mr Greenwood was accompanied by Sir Walter Kinnear and Sir George Newman After discussion, Mr GREENWOOD suggested that the deputation should confer with the full Parliamentary Medical Committee to ascertain whether medical members of Parliament would approve of an advisory body on rheumatism consisting of independent experts working in touch with the Ministry of Health in a manner analogous to the Cancer Council A memorandum submitted to the Minister by the deputation ran thus

"It is stated that one-sixth of the total invalidity for which insurance benefit is received is due to 'rheumatic diseases,' and that approximately one-half of this is due to rheumatic arthritis The cost of benefit paid for invalidity due to rheumatic disease in 1922 was approximately £1,000 000

"Rheumatism must no longer be considered an incurable disease A considerable proportion, especially of early cases, can now be permanently and completely cured, and many more can be markedly relieved by treatment

"Much remains to be learned regarding the causation and prevention of rheumatism Problems of this nature can only be successfully worked out where cases are collected together for study and investigation

"In view of the above facts centres for the treatment of rheumatic disease have been springing up in this and other countries Several are now in course of erection, and more are under consideration

"The systematized investigation and treatment of rheumatic disease is a relatively new subject, and the experience of other countries shows that serious mistakes are liable to occur unless full advantage is taken of the latest knowledge and experience

"Accordingly it is suggested that a small standing consultative committee be founded, composed of medical men engaged in the active practice of the methods of treatment adopted in rheumatic centres Such men should have knowledge of the trend of current British and Continental opinion and practice, in the investigation and treatment of rheumatic diseases

'All bodies public and private that propose the formation of centres for the treatment of rheumatic disease should be invited to consult this committee and submit schemes and plans to them for suggestions and advice

By the help of such a committee the co-ordination of centres which will shortly be springing up in many towns might be made possible and overlapping prevented Moreover, if each centre were encouraged to send in an annual report to the committee the experiences of all could be pooled"

Mr GREENWOOD stated in the House of Commons, in reply to Mr Graham White on May 3rd, that he was following with interest the progress of the clinic for the treatment of rheumatism established by the British Red Cross Society He understood it was now open for the treatment of all forms of chronic rheumatic diseases, and that there was an increasing attendance of patients

Road Traffic Bill

When the House of Commons considered the Road Traffic Bill on July 4th Dr SALTER moved to amend Clause 10, which deals with the rate of speed by inserting a maximum legal speed of 35 miles an hour He said he had been asked to move this amendment on behalf of the London County Council, as well as by the Pedestrians Association and the National Cyclists' Union Many urban district councils and borough councils were anxious that a speed limit should remain Fatalities on the road were increasing, and a principal cause was excessive speed by many motorists He pointed out that the bill did not provide tests of physical fitness or eyesight tests for motorists, nor any examination in the rules of the road Pedestrians were endangered while on the footpath, and at least three persons were killed each day while walking or standing there The introduction of the present bill, with the intimation that the speed limit was to be abolished had resulted in an increase of road accidents The number of cars on the road was increasing by 7 per cent per annum but the number of accidents by 15 per cent per annum, and the abolition of the speed limit would tend to make things worse

Mr HERBERT MORRISON, the Minister of Transport, said that Dr Salter's speech proved that the speed limit arrangements had broken down Speed was a factor in danger, but Dr Salter's amendment, if accepted, would cause it to be regarded as the only factor By the inculcation of a standard of good conduct among motorists more would be done than by setting up a standard of 35 miles an hour The Ministry of Transport proposed to encourage police authorities to provide a mobile police force mounted on motor cycles or in motor cars, and a contribution would be proposed for that purpose out of the Road Fund A highway code would be published to educate both motorists and pedestrians in good conduct

Dr Salter's amendment was defeated by 99 to 180, and further discussion of the bill was adjourned

Slum Clearance.

The Housing (No 2) Bill, the Government's measure dealing with slum clearance and the resettlement of slum dwellers, was before a Standing Committee of the House of Commons on July 1st, when its consideration was completed A general discussion arose on Clause 44—provisions with respect to official representations This provides that 'official representation" shall mean, in the case of any local authority, a representation made by a medical officer

Sir PHILIP PILDITCH argued that representations with regard to single houses and on smaller matters could properly be made by the sanitary inspector He pointed out that sanitary inspectors were full time officers, while last year there were 1,216 part time medical officers of health in England and Wales and only 358 whole time medical officers

Dr VERNON DAVIES said these part-time medical officers attended their offices every day of the week except Sunday The sanitary inspector was directly under the control and orders of the medical officer of health To make it possible for the sanitary inspector to present suggestions to the local authority over the head of the medical officer of health would cause difficulty between the two

Mr MCSHANE said no conflict of control had arisen from the Housing Act, 1925, which recognized the sanitary inspector

Mr GREENWOOD said the object of the bill was not to improve the status of sanitary inspectors

Further discussion then arose on the relations between the district and the county medical officer Dr VERNON DAVIES said the two officers always met as man to man The bill would cause friction by proposing that the county medical officer, after looking round a district, could report directly to the county council instead of seeing the district medical officer He moved an amendment providing that in urban districts with more than 10,000 of a population (against the 20,000 provided for in the bill) the county medical officer should not make representations to the local authority without consulting the district medical officer The Urban District Councils Association felt strongly that there should be no invidious distinction between urban districts and non-county boroughs in this matter

Miss LAWRENCE accepted the amendment, which was agreed to

The bill was reported to the House Subsequently, on July 8th, it passed through report and third reading

Silicosis—Mr CLYNES, replying on July 8th to Mr Jenkins, said that certain cases in which hardship was alleged to have been caused by the limitation of the scheme for compensation to miners suffering from silicosis to rocks containing more than 50 per cent of free silica had been brought to his notice Those cases were the subject of special inquiry arranged by the Mines

results of that investigation were available The returns so far received showed that there were twelve cases from coal mines in 1929 in which compensation was paid for silicosis He could not give the number of claims refused or the reasons for refusal

B C G Fatality at Lübeck.—Mrs LAWRENCE told Mr Freeman on July 8th that she could not state the result of the inquiries of the representatives of the Medical Research Council into the death of twenty infants in Lübeck Germany following the Calmette prophylactic treatment The Minister of Health however understood that a report to the Medical Research Council on the subject of those inquiries was in preparation

Experiments on Animals.—Replying to Mr Freeman on July 3rd Mr CURTIS stated that the number of experiments performed by vivisection during 1929 was 403 141 Experiments performed on dogs and cats under Certificates E and F E numbered 2 523 Inspectors were present during 157 cases involving operative procedure but these formed only a very small proportion of the whole number and the inspectors in the course of their visits saw and examined many animals under experiment

Status of Osteopaths.—Answering Mr Freeman on July 3rd, Mr GREENWOOD said he did not propose to introduce legislation to amend the Medical Act 1858 so as to procure recognition and independent regulation of osteopathy and give its qualified practitioners a legal status equivalent to that enjoyed by recognized professions

Neglect of a Schoolboy's Eyesight.—Replying to Mr Freeman on July 3rd Sir CHARLES TREVELYAN gave the facts concerning the case of a child at Broad Street School Bromley Kent who was alleged to have received forcible treatment for his eyes at school from a representative of the school medical officer and *without the consent of the parents* Sir Charles said that the boy was found on medical inspection to be suffering from a severe defect of the eyes and subsequently with the full knowledge of his parents attended the school clinic for a more thorough examination Drops were put in the boy's eyes to make examination possible but no treatment was given The parents were then advised that the boy needed spectacles but they refused to allow them to be provided In the last resort the National Society for the Prevention of Cruelty to Children initiated police court proceedings which resulted in the imposition of a fine for neglect (See *British Medical Journal* June 21st, p 1156)

Infectious Disease in Merchant Seamen.—Mr GREENWOOD, replying to Mr Lawrie on July 7th said that from 1890 to 1899 the yearly average of deaths (including non-civilians) from malaria dysentery and tuberculosis among British seamen in the mercantile marine was 7,648 and from 1900 to 1909 6 599 From 1911 to 1919 49,844 cases (excluding non-civilians) were notified and there were 4,922 deaths. From 1920 to 1929 54 484 cases were notified and there were 3 488 deaths. The first complete record of notifications of infectious diseases in England and Wales was for 1911.

Notes in Brief

The population of England and Wales on January 1st 1914, 1920 and 1930 was 37 770 000 37 379 000 and 39 653 0000 respectively

Mr Greenwood states that the Ministry of Health does not financially assist voluntary organizations dealing with functional nervous disorders in children or adults

Pending actuarial investigation of the position of asylum officers under the Asylum Officers Superannuation Act 1909 Mr Greenwood is unable to make any statement concerning amendment of that Act

Medical News.

PRINCESS MARY Countess of Harewood, will open Queen Mary's Hospital, Sidcup (formerly known as Queen's Hospital), at 3 p m on Monday, July 21st This is the first hospital to be acquired by the London County Council under the powers conferred upon it by the Local Government Act, 1929 it will be used as an auxiliary or recovery home for patients recovering from severe illness after treatment in the hospitals recently transferred to the Council

THE twelfth annual meeting of the Mental Hospitals Association will be held in the Council Chamber of the Guildhall, London, on Wednesday, July 16th, at 11 a m Papers will be read by Dr F R P Taylor, on after-care, by Dr P K McCowan, on out patient clinics, and by Dr W Robinson, *on a tour of the Scottish mental hospitals* In its report on the Mental Treatment Bill to be presented to the meeting the executive committee states 'While the measure does not meet with our entire approval, we nevertheless welcome it as a distinct endeavour to give effect to the recommendation of the Royal Commission on Lunacy and Mental Disorder that facilities should be provided for the early treatment of mental illness" Other subjects for discussion will be the registration of mental nurses and salaries of assistant medical officers to mental hospitals

FOUNDER'S DAY at Epsom College will be celebrated on Saturday, July 26th the second day of the annual cricket match between the College and Old Boys At noon there will be a service in chapel, and at 2.45 p m Viscount Burnham will present the prizes in the Big School After tea on the cricket ground there will be an assault at arms and in the evening a performance of "The Gondoliers by the Choral Society

THE Fellowship of Medicine announces that on Monday, July 14th Mr Mortimer Woolf will give a demonstration in the wards and out patient department of Queen Mary's Hospital, Stratford at 1 30 p m On Tuesday, July 15th at 2 p m Dr G Bourne will give a demonstration on children's diseases at the East London Hospital for Children No fees are charged for these demonstrations From July 21st to August 3rd a course in diseases of infants will be held at the Infants Hospital, Vincent Square, in the afternoons it will consist of lectures and demonstrations An all day course will be held at the Brompton Hospital from August 11th to 16th and another course at All Saints Hospital Vauxhall Bridge Road, will occupy the afternoons and early evenings from August 5th to 30th Apart from the special courses there is the general course of work, consisting of attendance at the ordinary clinical practice of some fifty London hospitals associated with the Fellowship it continues throughout the year and may be begun at any time Full particulars of all courses syllabuses, and specimen copies of the *Post Graduate Medical Journal* (published monthly 6s per annum, post free) may be obtained from the secretary of the Fellowship 1 Wimpole Street, W 1

THE London Temperance Hospital has now commenced building its new extension in Hampstead Road It is intended to erect a new wing for the pathological electrical, massage, and sunlight departments, and also to provide additional accommodation for the nursing staff and for private patients The carrying out of this work has been made possible by the *children grandchildren, and great grandchildren of the late* Mr and Mrs Samuel Insull, sen , who were associated with the hospital in its early days and took an active part in its work, together with their daughter, the late Miss Emma H. Insull

THE following members of the medical profession were called to the Bar on July 2nd Dr W S Russell Thomas (Lincoln's Inn), Dr F Baillie (Inner Temple), and Dr Peter K. McCowan (Gray's Inn)

THE Council of the Royal Institute of Public Health has accepted an invitation from the German Government the municipality of the City of Frankfurt, and the university of that city, to hold its congress in May, 1931, in Frankfurt The Marquess of Reading will preside

THE Board of Governors of the Hebrew University of Jerusalem announces that the children of Mr Felix and Mrs Frieda Warburg have established at the university a Fellowship in Public Health in the name of their parents The Fellowship (value L P 120) will be awarded annually to a young investigator who will be expected to devote his full time to research in the department of hygiene on a public health problem of special importance to Palestine Applications, stating references subject of investigation etc should be addressed to the Director Department of Hygiene, Hebrew University of Jerusalem, not later than August 31st

THE thirty fourth Congress of French speaking Alienists and Neurologists will be held at Lille from July 21st to 26th, under the presidency of Professor Abadie of Bordeaux when the following subjects will be discussed the cerebro-spinal fluid in mental disease, introduced by Dr Lamache of Paris, the elementary reflexes of posture introduced by Dr Delmas-Marselet, and the application of the insurance law to patients with mental disease, introduced by Dr Calmettes of Limoges

THE first International Congress of Microbiology will be held at the Institut Pasteur, Paris from July 20 h to 25th, under the presidency of Professor Bordet with Dr Roux as president of honour There will be three sections, devoted respectively to medical and veterinary microbiology ecology and immunology, and botany and parasitology The subscription is 100 francs which should be paid to the treasurer, 120, Boulevard St Germain, Paris Abstracts of communications should be sent to the general secretary Dr R Dujarric de la Rivière, Institut Pasteur, Rue Dutot 26 Paris XV

THE sixth International Medical Congress on Industrial Accidents and Diseases will be held in Geneva during August, 1931. All information may be obtained from the secretary of the British National Committee for this Congress, Mr G L Perry, Industrial Welfare Society (Incorporated) 51, Palace Street, Westminster S W 1

ACCORDING to the *Journal of the American Medical Association* the typhoid incidence and mortality in the United States continue to decline Not only was the typhoid death rate for 1929 in a city population of approximately 34 millions as low as 1 56 per 100 000 but the actual number of typhoid deaths in this population was lower than half the corresponding number in 1925 The number of diphtheria deaths reported in 1929 (2,648 for 81 cities with a population of about 34 millions) was also considerably lower than it has been for some years

THE annual sum allotted by the Reichstag for combating alcoholism and the dangers still connected therewith has been raised from 400 000 to 1 800 000 marks

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563,* and *9564* (internal exchange, four lines)

The ***TELEGRAPHIC ADDRESSES*** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Attiology Westcent London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc), *Articulate Westcent, London*

MEDICAL SECRETARY, *Mediocera Westcent, London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

BROMIDROSIS

"R B C" asks for suggestions as to the treatment of a public school boy, aged 14, who suffers from profuse perspiration of the feet, with a persistent objectionable odour, in spite of one or two baths daily

TREATMENT OF HAEMORRHOIDS BY INJECTIONS OF SODIUM MORRHUATE

DR A STANLEY ROSS (Edinburgh) asks for information about the treatment of haemorrhoids by the injection of sodium morrhuate 'I have used this preparation for injecting varicose veins in several cases recently with very good results I have also treated two cases of haemorrhoids of a severe type with it, with apparent relief'

TREATMENT OF JELLY-FISH STINGS

M B (Wales), while bathing last summer, was stung by a jelly-fish, the irritation was intolerable for hours afterwards Since he is going on holiday to the same resort this year suggestions for treatment would be acceptable

TREATMENT OF PRURITUS ANI

M R C S writes As a sufferer on several occasions my experience may be of service The patient should take neither wine nor malt liquor, but a little whisky, with plenty of water, is harmless Avoid spinach and greens and all fruits, except cooked apples and bananas, potatoes may be taken After defaecation wash with sponge and cold water, dry with Turkey twill towel and apply carbolized vaseline (1 in 5) every second or third day For the irritation the best thing is ung sorbefacions applied every two or three hours, it may be obtained from Thos Christy and Co, and contains menthol and boric acid in a basis of lanoline Better than a sanitary towel to avoid staining is an old silk handkerchief attached to a band round the body

SOLIDIFICATION OF MILK IN HOT WEATHER.

'LOWLANDER' writes On several occasions lately a patient of mine on heating milk in a cup placed in a saucepan has found that after a few minutes heating the milk goes almost semisolid and quite stringy" He changed his dairy but the same thing recurred *I should be grateful for an explanation of this phenomenon*

*** The phenomenon described is probably due to the rapid multiplication of organisms that occurs in milk during hot weather Within a few hours an originally good specimen of milk may contain ten or more million organisms per cubic centimetre Many of these organisms produce lactic acid, and in the presence of lactic acid very little heat is liable to produce clotting

CLOTHES MOTHS

H G writes I should be grateful if one of your readers would tell me of a remedy for the devastation to clothes, etc, caused by a plague of moths My flat is situated between shops which have a considerable amount of litter in the attached yards *We have tried the usual methods suggested but cannot keep down the number of moths, nor prevent the damage done,* although woollens clothing, etc, are frequently turned out, and then wrapped up in paper

*** Some correspondence on this subject in the pages of *Nature* was summarized in a note in our issue of December 8th, 1923 (p 1126) Some authorities threw doubt on the efficacy of camphor and naphthalene on the other hand, Mr James Ritchie of the Royal Scottish Museum, Edinburgh, gave references to the work carried out at the United States Department of Agriculture, which led to the conclusion that *naphthalene in* good condition is "one of the safest and best materials for protecting fabrics against moth injury" It must, however, be used in moderately tight receptacles, so that the fabrics remain in a naphthalene permeated atmosphere Mr Ritchie added *that camphor* used in the same way was said to be almost as effective, its fumes killing all stages of clothes moths

INCOME TAX

Charge for Clerical Work

"ARGENT" asks, "What is a reasonable salary to charge for my daughter, who does my clerical work?' The charge he proposes is £78 per annum, but the inspector of taxes will agree to £39 only

*** It is impossible to say definitely without knowing all the circumstances, but the answer, in general terms, seems to be the amount which "Argent would find it necessary to pay to a competent person willing to take on the work and reasonably anxious to earn money in that way We are assuming that the amount of clerical work is sufficient to make the employment of someone reasonably desirable to free "Argent" for actual work in the practice

LETTERS NOTES, ETC

VACATION EMPLOYMENT FOR UNDERGRADUATES

THE EARL OF DERBY writes [illegible] each summer [illegible] paid work to [illegible] and Canada the student who earns enough during the summer to contribute substantially towards his living expenses during the rest of the year is as often the rule as the exception In England, however, there is no tradition in favour of such employment, *and now that many students from the middle and working* classes find it necessary that they should make some contribution to the family exchequer, the difficulties in the way of their obtaining temporary paid posts are almost insuperable Partly this is the result of bad economic conditions and of the fact that students have no desire to displace ordinary labour The students' difficulties, however, are at least in part due to the reluctance of employers to employ undergraduates in a way with which the last generation was not familiar, and I feel that if more were known of the students seeking such employment, it would be found that there are many temporary posts which they could suitably occupy *In the present summer* many hundreds of students are looking for vacation work as secretaries, salesmen and saleswomen, farm workers, assistant engineers, guides, coaches, governesses and so on The National Union of Students, 3, Endsleigh Street, London, W C 1, is in a position to introduce suitable students to any employer who will apply to the secretary

OSTEITIS FIBROSA

DR J TERTIUS CLARKE (Harrow) writes In the *Journal* of July 5th (p 9) is a description by Drs J Salisbury Craig and James H Sheater of a case of osteitis fibrosa 'with initial symptoms resembling rheumatic infection I shall be much obliged if the authors will explain why it was considered that the initial symptoms resembled rheumatic infection

THE FOOT IN CLASSICAL SCULPTURE

DR GEORGE JONES (Lewisham) writes Apropos of the annotation on 'The foot and the shoe' (July 5th p 27), a cast from the Venus de Milo would show only the toes of the right foot A photograph of the statue is before me as I write, and a bronze over *3ft high is in the next room* The two *agree the left leg* and foot are entirely hidden by the drapery, which covers all but just the end of the right foot Perhaps the medical officer of health was thinking of the Medicean Venus in the octagonal room at Florence, generally known as the Tribuna, where there are, or were, two life size nudes There is a very fine but little known, collection of casts in the basement of the *British* Museum The way down to it is through the gallery on the ground floor, past the portrait statues of the Caesars

PATRICK MANSON HOUSE

MISS MILDRED WENYON secretary of the Royal Society of Tropical Medicine and Hygiene, writes. His Royal Highness the Prince of Wales has sent to our president a donation towards the memorial to Sir Patrick Manson, to which the Duke of York has already subscribed Some time ago you very kindly reminded your readers of this *plan to perpetuate the memory of* the Father of Modern Tropical Medicine, to whom we are all, directly or indirectly, so much indebted Just over £8,200 has been received, and further donations will be very gratefully acknowledged by the president of the Royal Society of Tropical Medicine and Hygiene, 11, Chandos St, Cavendish Square, W 1

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48 49, 50, 51, 52 53 54 55 59 and 60 of our advertisement columns, *and advertisements as to partnerships,* assistantships and locumtenencies at pages 56 and 57

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *16*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

29 Typhoid Fever in Infancy

A A WEECH and K T CHEN (*Amer Journ Dis Child*, November, 1929, p 1044), who record an illustrative case state that of 417 cases of typhoid fever up to the age of 2½ years, collected by Griffith and Ostheimer in 1902, 23 were congenital and 139 others occurred in the first year of life The course of the disease is much more variable in infants than in older children and adults Evidence of intestinal infection may be entirely lacking and the disease may present only the characters of a general blood infection Other cases, however may be of the usual type, with diarrhoea splenic tumour, and rose spots, and all kinds of complications including perforation and peritonitis The prognosis is generally regarded as more severe than when the infection occurs in later years Of the 139 cases collected by Griffith and Ostheimer, 77 patients died, 28 recovered and in 34 the result was not recorded The present case was that of a male Chinese infant aged 3 weeks, breast fed by his mother, who was suffering from typhoid fever, to the age of 6 days, after which he was suckled by a wet nurse The diagnosis was established by blood cultures, which were positive for *B typhosus* on two occasions The disease ran an extremely mild course failure to gain weight being the principal symptom The additional features were fever of only twenty four hours duration, slight splenic tumour an atypical eruption a lymphocytic leucocytosis, and a persistently negative Widal reaction

30 Pulmonary Asbestosis

W E COOKE and C F HILL (*Journ Roy Microsc Soc*, 1930 vol 1 p 15) refer to the first published case of pulmonary asbestosis recorded by Cooke in the *British Medical Journal* (1924 ii, 147), and state that the history of the condition dates from 1900, when asbestos spicules were found in a lung by Montague Murray, although the manufacture of cloth from asbestos had been an industry 2 500 years before that time In addition to fine black granular dust much of which is carbonaceous, and larger fragments of asbestos the lungs in pulmonary asbestosis show curious bodies in the alveoli, bronchioles, the fibrous and necrotic areas, and the phagocytes The larger bodies measure from 20 to 100 microns or more in length, they are of a golden brown colour and present the appearance of elongated dumb bells, filaments, or discs Investigation showed that the bodies consisted of central nuclei of asbestos spicules upon which colloidal aggregates of blood proteins, with, possibly, soluble fractions of asbestos (and in the case of chrysotile workers an iron salt), had been adsorbed and moulded by currents in the bronchi and alveoli The authors hold that these bodies if found in any numbers, are pathognomonic of pulmonary asbestosis

31 Normal Blood Pressure in Essential Hypertension

ESSEX TIAL hypertension is usually defined as a disease characterized chiefly by a persistent elevation of the blood pressure without known organic cause It is not generally realized that the condition may exist even though a normal blood pressure has been noted at one visit D AYLMAN (*Journ Amer Med Assoc*, April 19th 1930 p 1214) discusses the cause, frequency, and practical significance of normal blood pressure readings in essential hypertension A clear understanding of any blood pressure study necessitates a knowledge of the normal standards of the pressure and of its variability In the present study a blood pressure of from 120 to 135 systolic and from 80 to 89 diastolic between the ages of 20 and 60 was considered as the average normal a variation of more than 10 mm of mercury above these figures was taken as pathological The variability (called also fluctuation, lability, and instability) of the blood pressure is regarded by Kylin and Fahrenkamp as the outstanding characteristic of essential hypertension Ayman found that the instability of the blood pressure in essential hypertension will often lead to normal readings if the patient sits quietly for five to twenty minutes, this occurs even in patients with widespread vascular changes This finding was exhibited in 56 per cent of 76 unselected untreated cases Therefore, hypertension may apparently exist with normal blood pressure A wide range of circumstances such as physical and psychical rest tend to lower an elevated blood pressure From the ages of 30 to 60 the incidence of hypertension rises from 10 to 40 per cent and consequently from the age of 30 onwards search should be made for early hypertension In all young patients with signs or symptoms of vasomotor instability, especially with a family history of hypertensive disease, repeated examinations are necessary to detect the development of hypertension

32. Experimental Hypoglycaemia in Normal Individuals

A NORDSTED, A NORGAARD and T E HESS THAYSEN (*Acta Med Scand*, April 28th, 1930 p 125) record their observations on the hypoglycaemic symptoms in 20 normal individuals after the intravenous injection of 12 units of insulin The most prominent symptoms were the rise of the systolic and fall of the diastolic blood pressure, and an increase in the pulse rate The maximal changes in the blood pressure and pulse rate were found at the time when the hypoglycaemia ceased and the blood sugar concentration began to rise During the fall of the blood sugar curve the following symptoms were observed dizziness pallor fibrillary twitchings, fatigue drowsiness, general indisposition sweating, and occasionally motor excitement The sensation of hunger did not appear until the blood sugar curve began to rise The authors think that certain symptoms—namely, the pallor, changes in blood pressure, and acceleration of the pulse—are not directly caused by the hypoglycaemia, but mainly by increased suprarenal activity brought on by the hypoglycaemia Other endocrine glands, especially the hypophysis may also play a part in the production of the symptoms The term "insulinism" therefore, is preferable to "hyperglycaemic symptoms"

33. Alopecia Areata and Acute Infectious Diseases

S K ROSENTHAL (*Derm Woch*, May 3rd, 1930, p 612) records six cases, in men aged from 18 to 28 who developed alopecia areata after influenza, scarlet fever, tonsillitis, and typhoid fever respectively While some authorities hold that the cause of alopecia areata is to be found in disturbance of the central nervous system or of the endocrine vegetative apparatus others consider the affection as of parasitic origin Rosenthal on the other hand suggests that alopecia areata is an independent infection similar to herpes zoster or erythema nodosum, all three of which may appear in epidemic or sporadic form and as the sequel of various infectious diseases

Surgery.

34 Malignant Tumours of the Nail Bed

IN malignant tumours arising in the nail bed, according to R H JAFFE (*Surg, Gynecol and Obstet*, May, 1930, p 847) the early stages are often masked by a harmless appearance and insignificant symptoms, so that they may be overlooked This is well illustrated by a pigmented tumour which arises at the border of or beneath the nail Located between the nail and bone where there is very little soft tissue to permit its expansion the tumour destroys the nail and is often still small even when the regional lymph glands or distant organs have become invaded with metastases From a review of the literature it is concluded that melanotic tumours of the nail bed are rare, the majority were found on the fingers, and especially on the thumb These tumours are very malignant and usually come under observation after metastasis has occurred A case of a characteristic subungual melanoblastoma of the great toe and one of squamous celled carcinoma of the nail bed of the little toe are here recorded Malignant tumours of the nail bed can be easily distinguished from benign growths, because the latter do not break through the nail In distinguishing melanoblastoma from benign granulomata and carcinoma the demonstration of pigmented areas, which may be very small is of great importance in this situation carcinoma presents a dry waxy surface Malignant tumours of the nail bed occur at advanced ages no case has been reported under 35 and most patients are in the sixties or seventies In about half the cases trauma has preceded the neoplasm by an interval of one and a half to five years The prognosis is grave and the absence of local metastases does not exclude the involvement of internal organs The average length of life after the diagnosis is made is 14 months The treatment is an early radical operation x rays or radium are contraindicated Jaffé advises that ulcerative lesions of the nail bed in elderly persons which do not show any tendency to heal should be carefully examined for possible malignancy

35 Vasostomy in Acute Urethritis

F KIDD (*Brit Journ Vener Dis*, April, 1930, p 79) advocates vasostomy for early acute urethritis, and gives notes of five cases in which this procedure resulted in more rapid cure than would have been expected from prostatic massage and irrigation, and with almost dramatic rapidity in some instances The operation of incising the vas deferens can be performed under local anæsthesia, but until technical familiarity has been attained a general anæsthetic is held to be preferable Lavage of the vesiculæ with 5 per cent colloid silver is effective, and seems to eradicate the gono coccus better than any other antiseptic After the operation the patient is kept in bed for three or four days, during which time a daily posterior irrigation with weak per manganate solution is advisable, in most cases no further irrigation treatment is required While the operation is not to be advocated for universal use in early cases, since most clear up by irrigation treatment alone, it is useful for patients in whom irrigation causes haemorrhage, pain, and increased discharge, and in those cases where for marital reasons a rapid cure is essential It has also been found useful as a quick method of clearing up cases of intractable arthritis which do not react in a week or ten days to daily prostatic massage, posterior irrigations, and S U P 36 injections The author suggests that the method would prove particularly valuable in war time His technique consists in exposing the vas, washing out the vesiculæ, and stitching up the wound rather than leaving the vas exposed, he adds that if the hole in the vas is carefully closed the risk of sterility is very small, some surgeons, however, avoid cutting it, puncturing it instead with a needle

36 Cancer of the Ileo-cæcal Valve

P CARNOT (*Paris Méd*, April 5th, 1930, p 308) classifies this condition according as it involves the ileal or cæcal aspects of the valve In ileo valvular cancer there is generally a stenosis at the lower end of the ileum, with dilatation of the small intestine, narrowing of the large intestine, and a tendency to invagination of the small intestine into the large The stenosis may be progressive and slow, with alternate constipation and diarrhœa Koenig's syndrome is apparent in these cases, it consists of violent colicky pain, associated with waves of peristalsis, and terminating in borborygmi caused by the passage of fluids and gas through the narrowed orifice False ascites may be observed, due to accumulation of fluid and gas in the distended coils of the small intestine Central ballooning and tympanism of the abdomen, due to gas in the distended small bowel, with a surrounding area of dullness caused by the empty large bowel, is stated by the author to be diagnostic of stenosis of the lower end of the ileum When a radiological examination is made without barium the characteristic horizontal layers of fluid and gas are observed After the ingestion of barium considerably dilated coils of the small intestine come into view, with arrest of the barium at the valve, and very little escape into the large bowel After a barium enema the colon may appear distended from loss of tone, but no obstruction is observed in the colon or cæcum until the valve is reached There may be acute abdominal obstruction from spasm, from a foreign body engaging in the stenosis, from an enlargement of the neoplasm, and especially from an invagination of the ileum into the cæcum Immediate surgical intervention is indicated Cæco valvular cancer is characterized by the presence of a palpable tumour, with haemorrhage, gangrene, and anæmia, but no tendency to acute or chronic obstruction This type may be associated with ileo valvular carcinoma

37 Sympathetic Ramisection for Spastic Paralysis

R B WADE (*Journ of the Coll of Surg of Australasia*, March 1930 p 406) relates his experience of the operation of ramisection in 35 cases of spastic paralysis In 32 cases paralysis had occurred at or before birth, one patient had a post encephalitic condition with a Parkinsonian syndrome, and two had paralysis from gunshot wounds in the head Of the 35 cases, 12 had hemiplegia, 16 had paraplegia and 7 had more than two limbs affected The aim of the operation is to lessen the rigidity caused by the spastic paralysis, and in every one of the cases under review this was accomplished Full functional use of the limb cannot be obtained, but the greater range of movement gained is held to justify the operation Inco ordination is improved, but the spasm is not altered an operation is consequently, not recommended for a patient with a predominance of spasm For the relief of co ntractures or quasi contractures the treatment should con sist of tenotomy of the groups of contracted muscles followed by ramisection and re education In most cases there is some mental disorder, and in the low grades of intelligence no treatment should be undertaken, although in most cases definite mental improvement follows physical relief Better results are obtained in the lower limbs, since such fine co ordination is not needed as in the upper limbs, after rami section the lower limb is sometimes so improved as to be adequate for the normal daily routine, whereas in the case of the hand the improvement is seldom sufficient to enable a living to be earned The operation should be performed at the earliest possible age, before overaction by groups of muscles has arisen, and before bony deformities have occurred or habits of spasm developed In spastic paralysis the opera tion is confined to the sympathetic system in the cervical and lumbar regions As a result of reviewing the 35 cases the conclusion was reached that the operation of rami section, with tenotomy and re education, should be the operation of choice in cases of spastic paralysis

Therapeutics.

38 Salicylate Administration as a Cause of Acidosis

TOXIC symptoms following the administration of salicylates have for long been attributed to acidosis, and C C JOHNSON (*Journ Amer Med Assoc*, March 15th, 1930, p 784) has there fore investigated the occurrence of this condition by animal experiments Sodium and ammonium salicylates and acetyl salicylic acid in doses corresponding to the full therapeutic equivalents (1 gram per kg body weight) were given orally to the unanæsthetized animals and hypodermically to those anæsthetized, the latter method being used to correct any irregularities which might arise in gastric absorption Averages of all the data on all functions during each hour were tabulated on a percentage basis The control animals received 50 c cm of water by the mouth, or 5 c cm of physio logical saline solution hypodermically It was found that such administration of salicylates caused definite respiratory stimulation with depletion of the alkali reserve of the blood The hydrogen ion concentration remained unaltered, and acetone was not detectable in the urine These changes pointed to a fixed acid acidosis compensated by loss of carbon dioxide In four of eight cats which received sodium salicy late in full therapeutic doses definite increases in the lactic acid content of the blood lactate were correlated with signifi cant decreases in alkali reserve and respiratory stimulation, the other four cats showed no evidences of acidosis Johnson concludes, therefore, that in rheumatic fever there is every justification for combining twice the dose of sodium bicar bonate with the salicylates administered; in poisoning from any salicyl compound symptoms of acidosis may be expected, and treatment with sodium bicarbonate is rationally indicated The fact that no effects were produced by methyl salicylate and by cinchophen points, he believes, to a peculiarity of the salicylates in causing acidosis Except when single small doses are given, as in the case of a headache, an alkaline bicarbonate should be simultaneously administered to prevent local gastric irritation as well as to guard against acidosis

39 Complications in the Arsenical Treatment of Syphilis.

N BLACK (*Canadian Med Assoc Journ*, May, 1930, p 673) reports an unusual reaction in the course of the arsenical treatment of a case of syphilis A woman, aged 28, with a strongly positive Wassermann reaction received weekly injections of a salvarsan derivative for five weeks, the total amounting to about 3 grams Bruises then appeared on the shoulder and hip, and, later, petechial spots were seen elsewhere Sodium thiosulphate was administered, and one injection of mercury followed, but thirty six hours after it severe bleeding from the nose started, the gums, which were already sore, began to bleed, and there was blood in the stools Improvement followed transfusion, but a few days later the haemorrhage returned The patient was readmitted to hospital and the transfusion treatment con tinued, but the red and white cells rapidly diminished, together with the haemoglobin percentage, pyrexia was present and marked, mental dullness developed, and eventually she died from broncho pneumonia Black asks whether this is to be considered a case of benzol poisoning, or whether the condition is attributable to the mercury or arsenic There was no evidence of renal disease, which contraindicates mercurial poisoning, and chemists asserted that it was impossible in the case of this compound (neo salvarsan) for the benzol ring to have been split off and become free He therefore regards the condition as having been arsenical poisoning, although the usual signs were absent, and calls attention to the fact that there was a rather indefinite family history of disease of the blood forming organs While admitting the rarity of such an occurrence, the author comments on the danger of severe reactions occurring during or following the use of arsenical preparations

40 Treatment of Psychoses by Hypnotics

H WAGNEROVÁ and J PROKOP (*Bratislavské Lekarské Listy*, April 1930, p 246) report a series of 50 women suffering from psychoses who were treated with somnifen a solution of the diethylamine salts of allyl isopropyl barbituric acid and veronal 35 of these patients received intramuscular injections of the drug combined with morphine and scopolamine The injections were given every twenty four hours for two to fourteen days with the view of obtaining prolonged sleep or a condition of drowsiness The total dose of somnifen never exceeded 45 c cm and that of morphine scopolamine 10 c cm of a 1 per cent solution The series of injections was repeated when necessary The authors found that this treatment was particularly beneficial in psychoses accompanied by agitation but it was ineffective in depressive psychoses progressive schizophrenia and melancholia Somnifen produced no ill effects even in patients suffering from heart and kidney disease *The drug appeared to be useful also in certain cases* of acute psychosis when given by the mouth in doses of 15 to 30 drops twice daily

Laryngology and Otology

41 Trichloracetic Acid in Laryngeal Tuberculosis

CITING the good results obtained by STILL BOVIE SYSCHOW, and others with trichloracetic acid in laryngeal tuberculosis, B KATZ (*Amer Rev of Tuberculosis* May 1930 p 636) remarks that during twenty years of personal experience he has noticed the necessity of having an exact way of introducing the crystals into the larynx in order to avoid burns of the pharynx and healthy parts of the larynx By using an instrument devised by himself the drug can be applied to the affected part after anæsthetizing the larynx with a 10 per cent solution of cocaine This technique does not damage the healthy tissues, and the patient can attend to his business the treatments being repeated every fourth or fifth day Trichloracetic acid has a crystalline structure and melts very easily on exposure to the air Upon application to the tissue a white slough is formed which comes off in one or two days The advantages of this acid in laryngeal tuberculosis are its ease of application, the absence of inflammatory reaction, and the invariably good results in cases which are not hopeless from a general point of view It can be easily applied to those points of the larynx no easily reached with an electrocautery Control of the dysphagia and of oedema due to ulceration or ordinary oedema can be achieved with a few treatments Katz thinks that, in *pharyngeal and laryngeal tuberculosis trichloracetic acid* must be considered as a specific When tuberculomata are present in the larynx they should be gradually removed by repeated electrocauterization with subsequent applications of the acid The author emphasizes the fact that laryngeal tuberculosis is secondary to pulmonary tuberculosis reflecting the primary disease in its manifestations If, therefore, the *pulmonary condition is becoming progressively worse the* treatment of the laryngeal lesions is not encouraging whatever method is employed, though pain can be relieved with trichloracetic acid even when cure is out of the question In favourable cases it requires two to six months to arrest the disease depending on the individual degree of involvement In some cases with positive sputum relapses occur, and the treatment must be repeated

42 Otitis Media and Mastoiditis

I 1927 H I LILLIE (*Journ Amer Med Assoc* February 22nd, 1930 p 531) reported four cases in which early involvement of the blood stream from otitic and mastoid disease was treated by relatively conservative surgical measures without interfering with the sigmoid sinus or jugular vein, five further cases are now recorded in which the same measures were adopted In order to recognize early involvement of the blood stream in otitis media the patient must be observed carefully from the onset of the disease since the involvement may occur early Infection or the products of infection of suppurative *disease of the temporal bone may extend to the* venous sinuses by one of several methods direct absorption of the infection through the small vessels in the diseased mastoid sometimes without visible changes in the sinus wall, development of phlebitis of the sinus, without parasinous abscess, by continuity from the infected bone of the sinus groove direct extension into the sinus because of breaking down of the wall of the sinus by a parasinous abscess breaking down of the intima of the sinus by the disease process and onset of mural thrombosis or septic breaking down of obliterating thrombosis within the sinus It was assumed that in certain early cases even those in which septicæmia could be demonstrated by blood culture, the disease could be controlled by a complete mastoid operation and thorough exposure of the sigmoid sinus to eliminate the earliest stage of phlebitis from contact with the diseased bone The sinus plate may appear quite normal but its removal may reveal early visible changes in the sinus wall The tendency of the sinus to force itself into the smoothed edges of bone was not interfered with and the wound was packed lightly so as not to impede the formation of the natural barrier Lillie maintains that whether or not the sinus is to be ablated, and the jugular vein tied in cases where infection of the blood is found at the time of the original mastoid operation, depends on the type of the disease the general condition of the patient, and the pathological process encountered He believes that while no indicated in all cases early mastoid operation will prove a satisfactory measure in well chosen ones

43 Delayed Meningitis following Fracture of the Labyrinth.

F R NAGEP (*Rev de Laryngol d Otol et de Rhinol* February 15th 1930 p 107) comments on the importance of realizing that a patient may develop meningitis many months after having sustained a fracture of the skull involving the petrous portion of the temporal bone From microscopical investigations which he had made the author came to the conclusion that the danger of late meningitis only existed in those cases of fractured skull where there was a true fracture of the labyrinth which injury is only rarely followed by haemorrhage into the ear *Healing of such lesions is only observed* in those portions of the skull which are developed in cartilage and never in the membrane bones It is through this unhealed area that infection can find its way to the meninges from an otitis media which of course, may occur at any period It is now possible to diagnose these fractures by means of stereoscopic radiograms, and from the clinical syndrome of deafness and loss of vestibular function The treatment recommended is the radical mastoid operation with opening of the labyrinth at the earliest possible moment after signs of meningitis have become manifest

44 The Basal Metabolism in Ozæna

G CALOGERO (*Arch Ital di Otol, Rinol e Laringol* February 1930 p 89) examined the basal metabolism in twelve patients suffering from ozæna whose ages ranged from 11 to 35 Only three showed a lowering of the rate, indicating a condition of impaired function of the thyroid There was no relation between the severity of the ozæna and the metabolism rate, inasmuch as cases in which the rate was affected did not present a more severe form of ozæna than the others Nor was any close relationship found to exist between genital disturbances and changes in the basal metabolism In view of the frequency of ovarian disturbance in cases of ozæna and the comparative infrequency with which changes in the basal metabolism were observed, Calogero comes to the conclusion that ozæna has little or no influence on basal metabolism

Obstetrics and Gynaecology.

45 Carcinoma of the Body of the Uterus

IN an analysis of 100 cases of cancer of the body of the uterus W P HEALY and M CUTLER (*Amer Journ Obstet and Gynecol*, April 1930, p 457) discuss the relationship between histological structure and prognosis, and the comparative value of radiation and operation in the treatment of these tumours This condition is most common between the ages of 50 and 60 25 per cent of the cases occurring in nulliparæ Vaginal bleeding and discharge are the outstanding clinical symptoms Excluding adeno-acanthoma and adenomyocarcinoma four histological grades of carcinoma of the fundus can be defined, representing four degrees of potential malignancy Superficial papillary adenoma malignum (Grade I) is the most benign histological and clinical type Curetting and adequate intrauterine irradiation followed promptly by high voltage x ray therapy is the treatment of choice and offers an excellent prognosis in this group Adenoma malignum (Grade II) is the next in degree of malignancy 65 per cent cures result from radiation with or without hysterectomy The average duration of symptoms in this group was 19 months Adenocarcinoma (Grade III) is a more fatal disease than the preceding only 13 per cent of the cases being curable and the average duration of symptoms being thirteen months Diffuse or anaplastic carcinoma (Grade IV) is the most malignant type and the most radio-sensitive Only six patients several with advanced lesions were cured by radiation and combined radiation and hysterectomy Since no cures by surgery alone have been reported in this type, hysterectomy alone is distinctly contraindicated in this

group Adenocarcinoma is a more rapidly growing tumour than adenoma malignum, the difference in prognosis may therefore be explained by the difference in degree of malignancy as indicated by the rate of growth With the exception of Grade IV, fundus cancer is moderately radio resistant, radiation to be of benefit must therefore be supplied in an adequate amount The results obtained demonstrate the practical importance of adopting a suitable method of treatment in each type The prognosis following a primitive hysterectomy may be rendered more favourable by prompt irradiation of the cervical stump Inoperable cases, including those in which the operation presents technical difficulty, are best treated by radiation alone Intrauterine radiation is the method of choice in Grade I tumours, in the other three types radiation alone and combined radiation and hysterectomy have yielded approximately similar results The combined results in 82 operable cases, which show 58 5 per cent cures, compare favourably with the best surgical statistics The choice between radiation and operation in operable fundus carcinoma must for the present depend on each individual case, taking into account such factors as the histological type, technical operability, stage of disease, and the constitutional and local complications

46 Eclamptic Amaurosis

ACCORDING to F LOOSE and C SCHROEDER (*Zentralbl f Gynak*, April 19th, 1930, p 967), German opinion is divided as to the nature and significance of eclamptic amaurosis According to the older conception the sudden onset, the absence of visible lesions of the fundus oculi, and the preservation of the pupillary reflex prove that the blindness is of cerebral origin, residual organic lesions are never found Lindgren, however, in 1921 described cases of eclamptic amaurosis in patients who, although not having had an antecedent retinitis gravidarum, showed with the onset of their blindness morbid lesions of the retina demonstrable ophthalmoscopically More recently ophthalmologists have recorded retinal haemorrhages, occurring in about 10 per cent of cases of eclamptic amaurosis, as a sign of serious prognostic import Loose and Schroeder describe the case of a 7-para aged 32, previously healthy, who became suddenly blind eight to ten days before term Oedema of the legs and abdominal wall was present, the urine contained 12 5 per cent of albumin and numerous red blood cells, and the blood pressure was 110/190 mm Perception of light was present, and both pupils reacted normally, the fundi showed peripapillary oedema, arterial narrowing, and two retinal haemorrhages in the right eye Vaginal Caesarean section was performed two hours later, a left retinal haemorrhage followed, but the ophthalmoscopic appearances had returned to normal two months later Operative delivery in this case was undertaken chiefly on ophthalmological grounds, extensive and irreparable retinal damage, it was felt, was likely to occur during conservative treatment of the eclamptic toxicosis At the same time the retinal haemorrhages and the haematuria, together with the high blood pressure, indicated that the toxin had already damaged the blood vessels seriously, and those of the brain were likely to have been implicated soon

47 Complete Lacerations of the Perineum

DESPITE the general improvement in obstetrical practice, lacerations of the perineum through the sphincter ani and the rectum still occur L E PHANEUF (*Med Journ and Record*, April 16th, 1930, p 410) states that, in order to avoid these, one of three methods should be employed at the time of delivery perineotomy, episiotomy, and manual dilatation of the perineum and vagina Perineotomy, or median perineal incision, is recommended when the disproportion between the presenting part and vaginal outlet is not too great Episiotomy, or lateral perineal incision, should be employed when much room is required, as in difficult forceps operations Manual dilatation of the perineum and vagina, which should be performed slowly, systematically, and gently, is ideal for preparing the birth canal before version and extraction operations A complete laceration of the perineum should be repaired after the expulsion of the placenta, unless maternal complications render this inadvisable If the patient is not seen soon after delivery, at least three months should elapse before operating At this time involution has taken place, the oedema has disappeared, scar tissue has formed between the torn edges, and better results are obtained than when the operation is attempted a few days after labour Phaneuf's operative technique includes the following procedures The pelvic floor is opened by an H shaped incision, a flap of posterior vaginal wall is then raised and bluntly dissected from the levatores ani muscles The anterior rectal wall is picked up, stretched, and the torn edges united by interrupted sutures of linen thread the knots being tied within the bowel lumen The perirectal tissues are approximated over the first suture line by a continuous mattress suture of chromic catgut, and also by figure of eight sutures of the same material The rectal wound is thus closed in three layers, the torn ends of the sphincter ani muscles are dissected from the scar tissue, and united with a figure of eight suture The excess of the vaginal flap is resected, the levatores ani with their fascia are united by three interrupted sutures, and the external perineum is closed by interrupted sutures A carefully planned course of convalescent treatment, including dietetic and medical measures, is essential for satisfactory end results.

Pathology.

48 Immunity of the Newborn to Scarlet Fever

J PAUNZ and E OSOMA (*Jahrb f Kinderheilk.*, January, 1930, p 181) examined the blood in the umbilical cord of the newborn, and particularly those infants who had not taken any breast milk, so that immunity acquired by lactation could be excluded Three mothers with a negative Dick reaction were first examined for the antitoxin content of their blood serum, which was found to exceed one fifth of a unit per cubic centimetre, the blood in the umbilical cord of their newborn children also showed the same amount of antitoxin present The blood of three Dick positive mothers and their newborn infants was then examined, and none showed such an amount of antitoxin The conclusion is that the newborn children of immune mothers inherit a large quantity of antitoxin, while the children of mothers susceptible to scarlet fever do not Further evidence of the placental transmission of immunity to scarlet fever is that the amounts of antitoxin required for immunity are found in the newborn infants who have not been breast fed, and in whom, therefore, immunity as the result of lactation can be excluded In a second series of experiments the infants of Dick positive mothers were put to the breast of immune nurses or fed with their colostrum Examination showed that the small degree of antitoxin present in the infants' blood before being fed was not affected by the administration of breast milk or colostrum. The immunity of the newborn infant to scarlet fever is therefore entirely transmitted by the placental route

49 A Solid Anti-coagulant

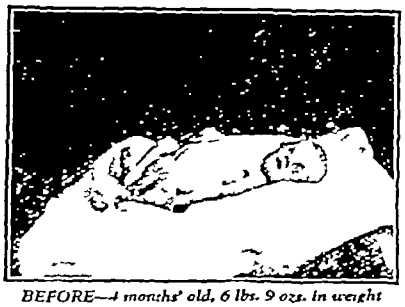
O NEUBAUER and H LAMPERT (*Munch med Woch*, April 4th, 1930, p 582), in searching for a substance which should have the anti coagulating properties of paraffined glass, without its disadvantages, investigated the properties of various substances in relation to their tendency to hasten or delay the coagulation of the blood They found that the degree to which a substance is moistened by watery fluids, such as water, blood, and serum, was, with few exceptions, in inverse ratio to the coagulation time of the blood in contact with it, they describe an exact method of measuring the degree of wetting In a series of tested substances it was found that glass and quartz became most wet and caused the most rapid clotting, whereas paraffin and soot were least moistened and delayed coagulation longest Polished metals, such as nickel, steel, and gold, were intermediate The ideal substance for practical use where clotting is to be avoided should have the properties of paraffin in this respect, but should also be suitable for making into flasks, syringes, etc It must therefore be hard, durable, transparent, sterilizable, and not too costly Such a substance Lampert claims to have found in a condensation product of phenol and formaldehyde, which he calls "athrombit", it is not so breakable as glass, is resistant to acids (but not alkalis), and is alkali free Using the same method and volume of blood in each case, the coagulation time at room temperature in glass was fifteen minutes, in athrombit forty minutes, in paraffin forty two to forty three minutes The authors describe a method for the transfusion of unaltered blood by means of vessels made from this substance and its use for the estimation of the coagulation time

50 Bacteriology of an Influenza Epidemic

E F TRAUT and R D. HERROLD (*Arch Int Med.*, March, 1930, p 412) found that cultures from the nasopharynx and sputum in the influenza epidemic of 1928 almost unfailingly gave a predominating growth of green producing streptococci associated with Gram negative diplococci The streptococci were pathogenic for mice and produced a toxin, skin tests with which suggested a means of detecting susceptible persons Vaccines made from these streptococci seemed to have the power of conferring immunity against the influenza infection The green producing streptococci for the most part reacted similarly in fermentation and bile stability tests The authors were unable to identify the *Bacterium pneumosintes* of Olitsky and Gates in any of their cultures, and in only one were they able to find Pfeiffer's bacillus.

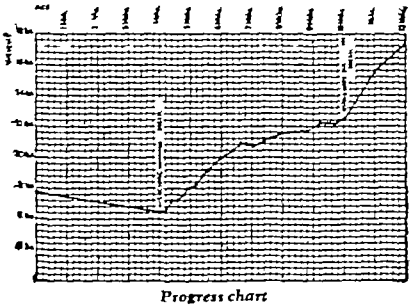
NATURALLY RICH

IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia The infant was put on to *LACIDAC* (Separated) with a small quantity of *BRESTOL* and immediately made steady progress.



At 6 months he had gained 3 lbs 7 ozs and by the end of another 4 months his weight was 12 lbs 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby

His Doctor considers him a '*Resurrection.*'

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

Progress chart

AFTER—10 months old 12 lbs 6 ozs. in weight

June, 1930 Baby 'H' has now won a prize in a Baby Show!

STANIFORM

Regd. BRAND Trade Mark

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLLTS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists Druggists Sundriesmen or Dental Supply Companies

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men

I continue to get every satisfaction from Staniform in the case of carbuncles boils whitlows and all kinds of infected wounds

In a case of acute eczema on leg the skin was quite normal within one week after starting application of Staniform Ointment

A left heel when first seen was about the size of a deal of pus Foot much swollen—dressed with Staniform healed splendidly in four days

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations inducing an immediate soothing effect with rapid healing
